“A reasonable starting point for a discussion of the many-body problem might be the question of how many bodies are required before we have a problem. Prof. G. E. Brown has pointed out that, for those interested in exact solutions, this can be answered by a look at history. In eighteenth-century Newtonian mechanics, the three-body problem was insoluble. With the birth of general relativity around 1910 and quantum electrodynamics in 1930, the two- and one-body problems became insoluble. And within modern quantum field theory, the problem of zero bodies (vacuum) is insoluble. So, if we are out after exact solutions, no bodies at all is already too many.”

In this work two important models of treating collisional absorption in a laser driven plasma are compared, the kinetic and the ballistic model. We will see that there exists a remarkable connection between these basic approaches which could give a hint how to overcome the inherent limitations.

Chapter 1

Introduction

For the prediction of collisional absorption - or inverse bremsstrahlung absorption - of electromagnetic radiation in a plasma the dynamics of collisions between particles have to be understood. The process of collisional absorption was of interest during a long time, as it is one of the fundamental heating mechanisms in laser or ion-beam driven plasmas. The progress in laser technology that makes short-pulse laser of high intensity available in experiments brought the interest up again, especially for the absorption of strong electromagnetic fields. From the theoretical point of view, the statistical non equilibrium properties of the collisional processes in the plasma make studying this field such attractive.

From the early works of Spitzer [1] and Braginskii [2] the collisional absorption rate, as well as the electron-ion collision frequency which relates to one-to-one, for static electric fields is well-known. Studies according to the high-frequency field were also made by Dawson and Oberman [3], by Perl’ and Eliashberg [4] and by Silin [5]. The collision frequency in strong fields, which was first discussed by Silin [5], recently has been restudied by Decker et al. [6]. Most of these works were limited to classical mechanics and the quantum correction entered only by an ad hoc cut-off - the De Broglie wavelength - which removes the divergency for small impact parameters in the collision integral. Quantum mechanical treatments were first given by Rand [7] and by Schlessinger and Wright [8]. A quantum approach in strong fields was also given by Silin and Uryupin [9]. A quantum mechanical dielectric treatment for arbitrary field strength was recently presented by Kull and Plagne [10] and also by Hazak et al. [11] the latter one including ion-ion correlations. Most of these works are based on the Vlasov equation - classical as well as quantum mechanical - including scattering by randomly distributed ions in first order perturbation theory. With the help of the more general Kadanoff-Baym equations including many-particle effects in dense plasmas, see Krempe et al. [12], the collision frequency was calculated by Bornath et al. [13]. A consistent treatment of dynamic screening at zero temperature was first done by Saemann and Mulser [14][15]. The publications mentioned above present the time-averaged absorption rate. Recently, Mulser et al. [16] have discussed the time-dependent absorption rate which was still missing in the literature. The theoretical results have also been confirmed by numerical simulations of the many-body system, see Pfalzner and Gibbon [18].

In our work we will follow at first the classical and the quantum kinetic approach based
on the first and the second equation of the BBGKY (Bogoliubov, Born, Green, Kirkwood, Yvon)-hierarchy. The hierarchy will be closed using the random phase approximation (RPA). Because the dielectric function of the plasma occurs in the RPA, this treatment is also called the dielectric model. We then will extend this approximation with the help of the ballistic model [16] which includes strong two-body collisions.

It is our main concern to achieve a single expression for the time-averaged collisional absorption rate valid in a large parameter region which no longer includes integrals or sums over an infinite range. Such an expression is still missing in the literature. Mostly the publications end up with expressions which are still very complicated. Only asymptotic approximations of those are presented in form of standard Coulomb logarithms.

1.1 The basic mechanism of collisional absorption

Imagine a homogeneous infinite plasma. It is considered to be quasi neutral, that is, if the ion density is $n_i$ we expect the electron density to be $n_e = Zn_i$, where $Z$ is the charge state of the ions. So, the overall electric and magnetic fields are zero. The plasma is disturbed by a time-dependent outer field, for example the oscillating electric field of a laser. The first process we observe is the oscillation of the electrons. In general, energy conversion between the electromagnetic field and matter is governed by Poynting’s theorem. The coupling between the field and the matter is expressed in the source term $\vec{j}\vec{E}$. In a time periodic electric field the cycle average of this term gives us the energy conversion rate, i.e. the absorption. As long as we assume total homogeneity the current density $\vec{j}(t)$ follows the electric field $\vec{E}(t)$ and the time average of the scalar product is zero. What we need is a phase shift between the current density and the applied field. This phase shift is induced by inhomogeneities in the density. One distinguishes between microscopic inhomogeneities, fluctuations, and macroscopic ones, density gradients. The second kind involves a large amount of particles and exists on the hydrodynamic or mean field scale leading to the so called collective absorption; whereas the first one has its origin in the graininess of matter and brings up collisional absorption. Our calculation model has to resolve the scale of graininess, that is, the particle-particle scattering has to be described. These scattering events give rise to the phase shift between the current density and the electric field.
Chapter 2

Kinetic Theory

In this chapter we will introduce the basic description of the plasma processes we are interested in. It is the non equilibrium kinetic theory based on the BBGKY-hierarchy. As this theory is well known only the specific parts which are important for our discussion will be mentioned. We will start with the classical theory and later we shall switch to the Wigner description of the quantum kinetic treatment. We shall take advantage of a symbolic, diagrammatic formalism to conserve the form of the equations in the classical as well as in the quantum mechanical case. The basic concepts can be found in [26][24][25][23].

2.1 The classical theory

2.1.1 The 2-particle distribution function

In the conventional way we write down the Liouville operator depending on the two-particle interaction potential $\Phi_{jk}$ and the potential of an external field $\Phi^{ex}$:

$$L_{1\ldots s} = \sum_{j=1}^{s} -\frac{i}{m} \vec{p}_j \frac{\partial}{\partial \vec{r}_j} + i \frac{\partial \Phi^{ex}}{\partial \vec{r}_j} \frac{\partial}{\partial \vec{r}_j} , \quad \mathcal{V}_{jk} = i \frac{\partial \Phi_{jk}}{\partial \vec{p}_j} \left( \frac{\partial}{\partial \vec{p}_j} - \frac{\partial}{\partial \vec{p}_k} \right) , \quad L'_{12} = L_{12} + \mathcal{V}_{12} .$$

The second equation of the classical BBGKY-hierarchy for the 2-particle distribution function is

$$\left( \frac{\partial}{\partial t} + iL'_{12} \right) f_2(1,2,t) = - \int d3 (i\mathcal{V}_{13} + i\mathcal{V}_{23}) f_3(1,2,3,t)$$

$$= I(1,2,[3],t) .$$

The momentum and position arguments of the distribution functions as well as the phase space integrals, including summation over particle species, are shortened by notating the particle number only.

In order to get a diagrammatic formalism, the following abbreviations are introduced:
Propagation of particles $j$ and $k$ for a time $+\tau$: $\uparrow_{jk} = e^{-i\int_0^\tau \mathcal{L}_{jk}}$

Propagation of particles $j$ and $k$ for a time $-\tau$: $\downarrow_{jk} = e^{+i\int_0^\tau \mathcal{L}_{jk}}$

Interaction of the particles $j$ and $k$: $\sim \sim = -i\mathcal{V}_{jk}$

Propagation and interaction of two particles:

Propagation and interaction of two particles in the mean field of a third one:

The differential equation for the 2-particle distribution function Eq. (2.2) can be transformed into an integral equation:

Using the defined symbols we get

This integral equation has to be solved by iteration. To do so we have to close the equation by finding a consistent approximation for the three-particle part. Before discussing this closure of the hierarchy we pay attention to the 2-particle operators.

2.1.2 2-particle operators

The propagator $e^{-i\int_\tau^t \mathcal{L}_{12}}$ includes the pair interaction as well as the external field. To examine in which way they act onto the 2-particle functions, we neglect the 3-particle part in Eq. (2.2),(2.3) and move the pair interaction to the right side:

If the external field is absent, $\mathcal{L}_{12} = \mathcal{L}^0_{12}$, the propagator $\uparrow_{12}$ is a pure shift operator,

$$\uparrow_{12} f_2(\vec{r}_1, \vec{p}_1, \vec{r}_2, \vec{p}_2) = f_2(\vec{r}_1 - \tau \vec{p}_1 m_1, \vec{p}_1, \vec{r}_2 - \tau \vec{p}_2 m_2, \vec{p}_2) \ .$$
describing the free propagations of the particles. It obviously separates into several one-particle parts, \( \tau_{12}^1 = \tau_{12}^1 \).

Writing Eq. (2.6) using the defined symbols,

\[
f_2(1, 2, t) = \tau_{12}^t f_2^0 + \tau_{12}^t \int_0^t \tau_{12}^\tau \sim \sim \sim f_2(1, 2, \tau) \, d\tau,
\]

and solving it by iteration, we find the known \textit{ladder}-diagrams:

\[
f_2(1, 2, t) = \quad + \quad + \quad + \quad + \, + \ldots
\]

The exponential form of this operator is built up by partial integration of the time integrals. In detail, setting \( F(\tau') = \int_0^{\tau'} \tau_{12}^\tau \sim \sim \sim \tau_{12}^{\tau''} \):

\[
\tau_{12}^\tau \sim \sim \sim \tau_{12}^{\tau''} \int_0^{\tau''} \tau_{12}^{\tau'} \sim \sim \sim \tau_{12}^{\tau''} = \frac{\partial F(\tau')}{\partial \tau'} F(\tau') = \frac{1}{2} \frac{\partial F^2(\tau')}{\partial \tau'}.
\]

The second form of the ladder-propagator, Eq. (2.10), is calculated by replacing the free propagator \( L_{12}^0 \) by the interaction one in Eq. (2.5) and solving the appropriate integral equation. The explicit expression of this propagator is quite complicated. It is no longer a pure shift operator as it contains the particle interaction. Nevertheless, as the 3-particle term is not included, this propagator describes the two-body problem of which the implicit solution is well known as long as no external field is switched on.

Using the above iteration scheme we could determine the free propagator including an external field depending on the time, but not on the position. The same procedure as before
in which the pair interaction is replaced by the Liouville operator of the electric field of the laser in dipole approximation,

$$\mathcal{V}_{12} = \mathcal{L}^{\text{ex}} = \sum_{j=1}^{2} i \frac{\partial \Phi^{\text{ex}}}{\partial \vec{r}_j} \frac{\partial}{\partial \vec{p}_j} = i \vec{E}(t) \left( q_1 \frac{\partial}{\partial \vec{p}_1} + q_2 \frac{\partial}{\partial \vec{p}_2} \right)$$

[q_1, q_2 charges of the particles],

leads us to:

$$\hat{\tau}_{12}^t = e^{-i \int_0^t \mathcal{L}^{\text{ex}}_{12}} = e^{-i \int_0^t \mathcal{L}^0_{12} + \mathcal{L}^{\text{ex}}_{12}} = e^{-i \int_0^t \mathcal{L}^0_{12}} e^{i \int_0^t \mathcal{L}^{\text{ex}}_{12}} e^{-i \int_0^t \mathcal{L}^0_{12}}$$

This propagator separates into 1-particle propagators, $\hat{\tau}_{12}^t = \hat{\tau}_1^t \hat{\tau}_2^t$, and acts as a shift operator in momentum and position, solving Newton’s equation. The calculation is done in detail in Appendix A and results in Eq. (A.1):

$$\hat{\tau}_i^t = e^{-(q_i \int_0^t \vec{E} \cdot \frac{\partial}{\partial \vec{p}_i})} e^{-\frac{1}{m_i} (t \vec{p}_i + q_i \int_0^t \vec{E} \cdot \frac{\partial}{\partial \vec{r}_i})}.$$  (2.11)

### 2.1.3 Discussion of the 3-particle part

To solve the integral equation for the 2-particle distribution function, Eq. (2.4), we have to find a closure due to the 3-particle source term. We extract the 3-particle correlation part

$$f_2(1,2) = f(1)f(2) + g_2(1,2)$$

$$f_3(1,2,3) = f(1)f(2)f(3) + f(1)g_2(2,3) + f(2)g_2(1,3) + f(3)g_2(1,2) + g_3(1,2,3).$$

Assuming that all particles are uncorrelated at the beginning, $g_2^0 = g_3^0 = \ldots = 0$ when supposing an ideal, fully ionized plasma in equilibrium, all correlations have to be built up dynamically through the processes we incorporate. Correlations due to the particle exchange symmetry, Fermi and Bose statistics, can be included by (anti)symmetrization of the pair operators [23]. This case will not be considered in this work as we assume that we are far away from the degenerated case.

If the average kinetic energy of the particles is much larger than the average potential energy, the interaction between the particles can be handled by the first order Born approximation. All graphs in which two particles are connected with more than one interaction line are neglected. The 3-particle correlation consists of all graphs in which three particles are irreducibly connected. To be consistent we have to neglect the contribution of $g_3$ in $I(1,2,[3],t)$ because these parts of $I(1,2,[3],t)$ would contain second order interaction terms. For example, the contribution of the most simple diagram of $g_3$ is:

$$\int d^3 \left( i\mathcal{V}_{13} + i\mathcal{V}_{23} \right) = [ \ldots ] = 0.$$  (2.12)

Based on this approximation the integral equation (2.4) can be solved. It results in the sum of all diagrams which contain only one interaction line between two 1-particle propagators, the well known Random Phase Approximation (RPA) [26][24][25][23]:

$$f_2(1,2,t) = \left[ \ldots + \ldots + \ldots \right] + \ldots$$  (2.12)
CHAPTER 2. KINETIC THEORY

The calculation is shown in detail for the 1-particle distribution function in Appendix B.

2.1.4 Beyond the weak correlation assumption

The approximation discussed in the preceding section does not mean that \( g_3, g_4, \ldots \) are all set equal to zero. The correlations in every order of the particle count are included, but the pair interaction only appears in first order. This is the weak correlation or weak coupling assumption. Now the question arises if we are able to go beyond this approximation. The answer is, that - under some conditions - a little step forward can be done.

The ladder operator introduced in Section (2.1.2) contains the pair interaction in every order and solves the two-body problem exactly. It builds up the two-particle correlation \( g_2 \) neglecting a third particle. As long as the external field is zero we know the solution. The RPA approximation contains \( g_2 \) only in first order. By replacing the two-particle correlation in RPA by the ladder graphs we get

\[
f_2(1, 2, t) = \begin{pmatrix} + & - & + & - & + & - & \cdots & + & - & \cdots \end{pmatrix} + \ldots \tag{2.13}
\]

Such a mixed model was successfully applied by Gericke and Schlanges [19] on the investigation of the stopping power of ion-beams in dense plasmas. The combined model which will be introduced in Section 3.3 is based on the same approach.

This mixture of the RPA and the two-body approach leads to an improved description of particles of low kinetic energy because strong two-body collisions are included. Comparing the quantities which characterize the Coulomb interaction in a plasma

impact parameter of perpendicular deflection \( b_\perp = \frac{Ze^2}{4\pi \varepsilon_0 m_e v^2} \)

screening length, Debye length \( \lambda_D = \frac{v}{\omega_p} = v \left( \frac{n_e e^2}{\varepsilon_0 m_e} \right)^{-1/2} \)

a first estimate of the validity of the model can be given.

i) \( \text{The impact parameter for perpendicular deflection } b_\perp \text{ should be much smaller than the average ion-ion distance } n_i^{-1/3} \text{ to exclude strong many-body collisions.} \)

This leads, again as in the RPA approximation, to the average kinetic energy should be large in comparison with the potential energy. Nevertheless, the small amount of strong two-body collisions is treated more realistically, by which, besides the De Broglie wave length, the singularity in the collision integral for small impact parameters is removed. Further, we are able to weaken the forgoing condition:

ii) \( \text{As long as the screening length } \lambda_D \text{ is smaller than the average ion-ion distance } n_i^{-1/3} \text{ the first condition i) can be violated.} \)

That means, the electron interacts with one ion only, the rest of the ions is screened. For this reason, the mixed model remains valid for a large range of plasma parameters. If the screening length reaches the ion-ion distance, the impact parameter for perpendicular deflection is still smaller than the ion-ion distance: \( (n_e = Zn_i), \lambda_D = n_i^{-1/3} \Rightarrow b_\perp = n_i^{-1/3}/4\pi \approx 0.08n_i^{-1/3}. \)
CHAPTER 2. KINETIC THEORY

2.2 The quantum kinetic extension

At first inspection, the quantum kinetic approach seems to be very different compared to the classical one. But if we choose the Wigner representation the form of the equations will remain the same, only the interaction operators will be obviously different. The transition from the quantum mechanical BBGKY-hierarchy in coordinate representation to the Wigner representation is shown in Appendix C.

We write the second equation of the BBGKY-hierarchy in Wigner representation (spin variables are suppressed):

\[
\left( \frac{\partial}{\partial t} + \frac{p_1}{m_1} \frac{\partial}{\partial R_1} + \frac{p_2}{m_1} \frac{\partial}{\partial R_2} \right) f_2(R_1, p_1, R_2, p_2, t) + \frac{i}{\hbar} (F_{12} + F_1^{\text{ex}} + F_2^{\text{ex}}) = \frac{i}{\hbar} (F_1^3 + F_2^3) \quad (2.14)
\]

with \([R_{12} = R_1 - R_2, \ r_{12} = r_1 - r_2]\)

\[
F_{12} = \int \frac{d^3r_{12}}{(2\pi\hbar)^3} d\eta_1 e^{-\frac{i}{\hbar}(p_1 - \eta_1) r_{12}} \left( \Phi(R_{12} + \frac{r_{12}}{2}) - \Phi(R_{12} - \frac{r_{12}}{2}) \right)
\]

\[
\times f_2(R_1, \eta_1, R_2, p_2 + p_1 - \eta_1, t) \ ,
\]

\[
F_1^{\text{ex}} = \int \frac{d^3r}{(2\pi\hbar)^3} d\eta_1 e^{-\frac{i}{\hbar}(p_1 - \eta_1) r} \left( \Phi^{\text{ex}}(R_i + \frac{r_i}{2}, t) - \Phi^{\text{ex}}(R_i - \frac{r_i}{2}, t) \right)
\]

\[
\times f_2(R_1, \eta_1, R_i, p_i, t) \ ,
\]

\[
F_2^{\text{ex}} = \int \frac{d^3r_3}{(2\pi\hbar)^3} d\eta_3 dR_3 e^{-\frac{i}{\hbar}(p_3 - \eta_3) r_3} \left( \Phi(R_{13} + \frac{r_i}{2}) - \Phi(R_{13} - \frac{r_i}{2}) \right)
\]

\[
\times f_3(R_1, \eta_1, R_3, p_3, t) \ .
\]

The binary interaction operator is

\[
\sim_{-+} = \sim_{+-} \sim_{--} = \sum_{\pm} \sim_{\pm}
\]

\[
\sim_{\pm} = \pm \frac{1}{i\hbar} \int \frac{d^3r_{12} d\eta_1}{(2\pi\hbar)^3} e^{-\frac{i}{\hbar}(p_1 - \eta_1) r_{12}} \Phi(R_{12} \pm r_{12}/2)
\]

\[
= \pm \frac{1}{i\hbar} \int dk \Phi_k \int \frac{d^3r_{12} d\eta_1}{(2\pi\hbar)^3} e^{-\frac{i}{\hbar}(p_1 - \eta_1) r_{12}} e^{ik(R_{12} \pm r_{12}/2)}
\]

\[
= \pm \frac{1}{i\hbar} \int dk \Phi_k \int \frac{d^3r_{12} d\eta_1}{(2\pi\hbar)^3} e^{-\frac{i}{\hbar}(p_1 - \eta_1 \mp \hbar k/2) r_{12}} e^{ik R_{12}}
\]

\[
= \pm \frac{1}{i\hbar} \int dk \Phi_k \int d\eta_1 \hbar \delta(\eta_1 - p_1 \pm \hbar k/2) e^{ik R_{12}}
\]

The last step in the above calculation can be done, due to the operator \(\sim_{\pm}\) acting onto functions with a dependency of \(f_2(R_1, \eta_1, R_2, p_2 + p_1 - \eta_1)\). These are independent of \(r_{12}\). So, the interaction potential \(\Phi_{12}\) in Eq. (2.14) can be written as

\[ f_2 = \sum_{\pm} \sum_{\pm} f_2 \]  

(2.15)

\[ \ldots f_2 = \sum_{\pm} \sum_{\pm} f_2 \]

\[ \ldots = \sum_{\pm} \sum_{\pm} \frac{1}{i \hbar} \int dk \Phi_k \int d\eta_1 \delta(\eta_1 - p_1 \pm \hbar k / 2) e^{i k R_{12}} f_2(R_1, \eta_1, R_2, p_2 + p_1 - \eta_1) \]

\[ \ldots = \frac{1}{i \hbar} \int dk \Phi_k e^{i k R_{12}} f_k^- (R_1, p_1, R_2, p_2) \]

\[ \ldots = \frac{1}{i \hbar} \int dk \Phi_k e^{i k R_{12}} \left( e^{\frac{\hbar}{2} (\frac{\partial}{\partial p_1} - \frac{\partial}{\partial p_2})} - e^{-\frac{\hbar}{2} (\frac{\partial}{\partial p_1} - \frac{\partial}{\partial p_2})} \right) f_2(R_1, p_1, R_2, p_2) \]

\[ \ldots = \frac{2i}{\hbar} \int dk \Phi_k e^{i k R_{12}} \sinh \left[ \frac{\hbar k}{2} \left( \frac{\partial}{\partial p_1} - \frac{\partial}{\partial p_2} \right) \right] f_2(R_1, p_1, R_2, p_2) \]

with

\[ f_k^- (R_1, p_1, R_2, p_2) = f_2(R_1, p_1 - \hbar k / 2, R_2, p_2 + \hbar k / 2) - f_2(R_1, p_1 + \hbar k / 2, R_2, p_2 - \hbar k / 2) \]

The transition to the classical expression is easily done by an expansion of the sinh-term up to first order of \( \hbar \).

Also, the three-particle terms \( F_{i}^3 \) and the external Potentials \( F_{i}^{ex} \) in Eq. (2.14) can be written as

\[ F_{i}^3 = \frac{2i}{\hbar} \int dR_3 dp_3 \int dk \Phi_k e^{i k R_{13}} \sinh \left[ \frac{\hbar k}{2} \left( \frac{\partial}{\partial p_1} - \frac{\partial}{\partial p_3} \right) \right] f_3(R_1, p_1, R_i, p_i, R_3, p_3) \]

\[ F_{i}^{ex} = \frac{2i}{\hbar} \int dk \Phi_k e^{i k R_{i}} \sinh \left[ \frac{\hbar k}{2} \frac{\partial}{\partial p_i} \right] f_2(R_1, p_1, R_i, p_i) \]

In case the external force depends on the time only, as e.g. the electric field of the laser in dipole approximation, the above expression for \( F_{i}^{ex} \) reduces to the classical one:

\[ F_{i}^{ex} = q_i \vec{E}(t) \frac{\partial}{\partial \vec{p}_i} f_2(R_1, p_1, R_i, p_i) \]

The quantum kinetic equation for the 2-particle Wigner function now reaches the same structure as the classical one, Eq. (2.4):

\[ f_2(1,2,t) = \gamma_{12}^t f_2^0 + \gamma_{12}^{\tau} \int_0^t \gamma_{12}^{\tau} \sim \sim f_2(1,2,\tau) \, d\tau \]

\[ + \gamma_{12}^t \int_0^t \gamma_{12}^{\tau} \int d3 \left( \gamma_{12}^{\tau} + \gamma_{12}^{3} \right) f_3(1,2,3,\tau) \, d\tau \]

(2.16)

with

\[ \gamma_{12}^t = \frac{2i}{\hbar} \int dk \Phi_k e^{i k R_{12}} \sinh \left[ \frac{\hbar k}{2} \left( \frac{\partial}{\partial p_1} - \frac{\partial}{\partial p_2} \right) \right] \]

(dipole approx., Eq. (2.11))

\[ \gamma_{12}^{\tau} = e^{-q_1 \int_0^\tau \vec{E} \cdot \vec{p}_i \gamma_{\vec{p}_i}^t} e^{-\frac{1}{\hbar} \int_0^\tau (\vec{p}_i + q_1 \int_0^\tau \vec{E} \cdot \vec{p}_i \gamma_{\vec{p}_i}^t) \cdot \vec{p}_i \gamma_{\vec{p}_i}^t} \]
This is straightforward for all the levels of the BBGKY-hierarchy. The discussions about the closure of the hierarchy in the preceding sections remain valid.
Chapter 3

Different Models of Collisional Absorption

In the following chapter two models for calculating energy absorption in a laser plasma will be presented. Each model is valid under the following assumptions:

- The electric field of the laser is treated in dipole approximation. The magnetic field is neglected.
- The electron and ion motion is nonrelativistic.
- We will use the test particle assumption: The ion distribution is described as one delta-like ion plus a homogenous background. This approximation is based on the assumption that only weak many-body collisions occur. These are described in first Born approximation which allows the independent summation over the collision events. (See the discussion in Sec. 2.1.4.)
- The plasma is not degenerate, $T_e > T_{\text{Fermi}}$.

3.1 The kinetic treatment

We calculate the energy absorption by using the RPA results from appendix B. We work on the quantum kinetic expressions. The classical result is easily obtained by the limit $\hbar \to 0$. The absorbed energy density of the electrons at a time $t$ in general is given by the scalar product of the current and the electric field, $\dot{\mathcal{E}}(\vec{r}_e, t) = \vec{j}_e(\vec{r}_e, t) \vec{E}(\vec{r}_e, t)$. We split the electric field into the oscillating laser part $\vec{E}_L(t)$, the Coulomb field of the ion $\vec{E}_c(\vec{r}_e)$ and the induced field generated by the disturbed electron density $\vec{E}_I(\vec{r}_e, t)$. In addition, the electron current is separated into a free oscillating part $\vec{j}_o(t)$ and an induced one $\vec{j}_I(\vec{r}_e, t)$. We now refer to the reference system of the free oscillating electrons. In the expression for the absorbed energy density the oscillating parts of the electric field and the current vanish. The time dependence of the laser field translates the time dependence of the Coulomb field of the ion because in the comoving frame the ion oscillates. We get

$$\dot{\mathcal{E}}(\vec{r}_e, t) = \vec{j}_I(\vec{r}_e, t) \vec{E}_c(\vec{r}_e, t) + \vec{j}_I(\vec{r}_e, t) \vec{E}_i(\vec{r}_e, t) = \dot{\mathcal{E}}^{(1)} + \dot{\mathcal{E}}^{(2)}.$$

13
The second term is of second order in the induced electron density, so we neglect it. Due to the system change the zeroth order \( \vec{j}_{os}(t) \vec{E}_L(t) \) does not appear which has no further meaning as the cycle average of this term is zero.

The system change applies onto the electron distribution function \( f_{e}^{qu} \), Appendix B [Eq. (B.5)], due to

\[
\vec{p}_e \to \vec{p}_e - e \int_0^t \vec{E}_L(\tau) \, d\tau, \quad \vec{r}_e \to \vec{r}_e - \frac{e}{m_e} \int_0^t \int_0^\tau \vec{E}_L(\tau) \, d\tau.
\]

Considering the action of the shift operator \( t' \), Eq. (2.11), the electron distribution function in the oscillating system assumes the form

\[
f_{e}^{qu}(\vec{r}_e, \vec{p}_e, t) = f_0^0(p_e) - \frac{2n_e^0}{h(2\pi)^{3/2}v_e^2m_e^2} \int_0^t \int \frac{d^3k}{(2\pi)^3} \Phi_{e}^{qu}(\vec{r}_0, \vec{k}, \tau) 
\times e^{-ik(\vec{r}_e - \frac{\tau - \tau'}{m_e} \vec{p}_e)} e^{-\frac{\vec{k}^2}{2m_e^2} - \frac{i^2}{2m_e} \sinh \left( \frac{\vec{k} \vec{p}_e}{k_B v_e m_e} \right)}.
\]

Before calculating the current we make some further simplifications. i) We shift the zero point of the time to minus infinity and assume that the laser is smoothly switched on: \( \int_0^t \to \int_0^\infty \), \( \tau \to t - \tau \). Thereby we lose the transient time behavior at the beginning which is of no high interest. ii) The ion temperature is set to zero. iii) The ion mass is set to infinity. iv) The ion position in the lab frame \( \vec{r}_0 \) is set to zero.

Using a Fourier expansion for the phase factors containing the electric field \( \vec{E}_L(\tau) = \vec{E}_0 \cos \omega_0 \tau \)

\[
e^{-ik\eta_{ei}(\tau)} = \sum_{l=-\infty}^{l=+\infty} e^{-ik\eta_{ei}(\tau)} = e^{ik\frac{s}{m_e} \int \vec{E}_L(\tau')} = e^{ik \frac{s \vec{E}_0}{m_e \omega_0} \cos \omega_0 \tau} = e^{ik \vec{r}_{os} \cos \omega_0 \tau}
\]

the effective potential, Eq. (B.9), expands to

\[
\Phi_{e}^{\text{eff}}(\vec{k}, \tau) = \int_{c-i\infty}^{c+i\infty} \frac{ds}{2\pi} e^{s\eta} \frac{\Phi_{e}^{ei}(k)}{\epsilon(k, s)} \sum_{l=-\infty}^{l=+\infty} e^{il\omega_0 \tau} J_l(\vec{k} \vec{r}_{os}) \frac{J_l(\vec{k} \vec{r}_{os})}{\epsilon(k, il\omega_0)}.
\]

We consider a stable plasma, that is, the zeros of \( \epsilon(k, s) \) are damped. So the poles at \( s = il\omega_0 \) determine the time behavior of \( \Phi_{e}^{\text{eff}}(\vec{k}, \tau) \)

\[
\Phi_{e}^{\text{eff}}(\vec{k}, \tau) = \Phi_{e}^{ei}(k) \sum_{l=-\infty}^{l=+\infty} e^{il\omega_0 \tau} \frac{J_l(\vec{k} \vec{r}_{os})}{\epsilon(k, il\omega_0)} J_l(\vec{k} \vec{r}_{os})\frac{J_l(\vec{k} \vec{r}_{os})}{\epsilon(k, il\omega_0)}.
\]

Calculating the induced current of the electrons \( \vec{j}_e^{qu} = -\frac{e}{m_e} \int d^3p_e \vec{p}_e \hat{f}^{qu} \) leads to

\[ \tilde{\mathcal{J}}_{1e}^u(\vec{r}_e,t) = \frac{e n_0}{m_e} \sum_{l=-\infty}^{l=+\infty} i^l e^{i\omega_0 t} \int \frac{d^3 k}{(2\pi)^3} e^{-ik\vec{r}_e} \frac{\Phi_{el}(k)}{\epsilon(k, il\omega_0)} J_l(k\vec{r}_e) \]

\[ \times \int_0^\infty d\tau e^{-il\omega_0 \tau} e^{-\frac{1}{2}k^2v_e^2\tau^2} \left[ \cos \left( \frac{k_v r_e \tau}{k_B} \right) - k_nv_e \tau \sin \left( \frac{k^2v_e \tau}{k_B} \right) \right] \]

\[ = \frac{e n_0}{m_e v_e} \sqrt{\frac{\pi}{2}} \sum_{l=-\infty}^{l=+\infty} i^l e^{i\omega_0 t} \int \frac{d^3 k}{(2\pi)^3} e^{-ik\vec{r}_e} \frac{\Phi_{el}(k)}{\epsilon(k, il\omega_0)} G^u(k, l\omega_0) \]

with

\[ G^u(k, \omega) = \frac{k_B}{2v_e} \omega^2 e^{-\frac{1}{2} \left( \frac{v_e}{v_e} - \frac{k}{k_B} \right)^2} \]

\[ \times \left[ \text{erfc} \left( \frac{i\omega}{\sqrt{2k}v_e} - \frac{ik}{\sqrt{2k_B}} \right) - e^{-\frac{2\omega}{\sqrt{2k}}} \text{erfc} \left( \frac{i\omega}{\sqrt{2k}v_e} + \frac{ik}{\sqrt{2k_B}} \right) \right]. \]

In the classical limit, \( \hbar \to 0 \) or \( k_B \to \infty \), the function \( G^u(k, \omega) \) strongly simplifies to

\[ G(k, \omega) = \left( \frac{\omega}{kv_e} \right)^2 e^{-\frac{1}{2} \left( \frac{v_e}{v_e} \right)^2} \text{erfc} \left( \frac{i\omega}{\sqrt{2k}v_e} \right). \]

The total energy absorption rate per ion in RPA approximation can now be determined by

\[ \dot{E}^u_{\text{RPA}}(t) = \int d^3 r_e \tilde{\mathcal{J}}^u_{1e}(\vec{r}_e,t) \vec{E}_c(\vec{r}_e,t) \]

\[ = \frac{Ze}{4\pi \epsilon_0} \int d^3 r_e \tilde{\mathcal{J}}^u_{1e}(\vec{r}_e,t) \frac{\vec{r}_e - \vec{r}_i(t)}{|\vec{r}_e - \vec{r}_i(t)|^3} \]

\[ = -\frac{Ze^2 n_0}{\epsilon_0 m_e v_e} \sqrt{\frac{\pi}{2}} \sum_{l=-\infty}^{l=+\infty} i^l e^{i\omega_0 t} \int \frac{d^3 k}{(2\pi)^3} e^{-ik\vec{r}_e} \frac{\Phi_{el}(k)}{\epsilon(k, il\omega_0)} \frac{J_l(k\vec{r}_e)}{k} G^u(k, l\omega_0) \]

Due to the oscillating reference system the position of the ion is \( \vec{r}_i(t) = \frac{eE_0}{m_e \omega_0^2} \cos \omega_0 t \).

We fix the electric field of the laser in z-direction, \( \vec{E}_0 = E_0 \hat{e}_z \). The above expression depends now on \( k_z \) and \( k \) only. In spherical coordinates we have \( k_z = k \cos \theta, d^3k = k^2dk \sin \theta d\theta d\phi \) and the \( k \) integration simplifies to

\[ \dot{E}^u_{\text{RPA}}(t) = -\frac{Ze^2 n_0}{\epsilon_0 m_e v_e} \sqrt{\frac{\pi}{2}} \sum_{l=-\infty}^{l=+\infty} i^l e^{i\omega_0 t} \int_0^\infty dk \frac{k \Phi_{el}(k)}{(2\pi)^2} \frac{J_l(k\vec{r}_e)}{\epsilon(k, il\omega_0)} G^u(k, l\omega_0) \]

\[ \times \int_{-1}^{1} dx e^{-ikr_{ox} \cos \omega_0 t} J_l(kr_{ox}) \]

\[ = -\frac{Ze^2 n_0}{\epsilon_0 m_e v_e} \sqrt{\frac{\pi}{2}} \sum_{l,m=-\infty}^{l,m=+\infty} (-1)^m \frac{m}{l+m} i^{l+m} e^{i(l+m)\omega_0 t} \int_0^\infty dk \frac{k \Phi_{el}(k)}{(2\pi)^2} \frac{J_l(k\vec{r}_e)}{\epsilon(k, il\omega_0)} G^u(k, l\omega_0) \]
\[ \pi \text{ simplifies to static part } \square \text{ quantum mechanical as well as in the classical case} \]

For real and imaginary parts (\( \mathcal{R}, \mathcal{I} \)) of the functions \( \mathcal{G} \) and \( \epsilon \) we find (\( k, \omega \) real) in the quantum mechanical as well as in the classical case

\[ \mathcal{R}\{G^{\text{in}}(k,\omega)\} = \frac{k_B}{\nu_e k^2} e^{-\frac{1}{2}} \left( \frac{\omega}{k_B \nu_e} \right)^2 e^{-\frac{1}{2}} \left( \frac{k}{k_B} \right)^2 \sinh \left( \frac{\omega}{k_B \nu_e} \right) \quad (3.5) \]

\[ \mathcal{I}\{G^{\text{in}}(k,\omega)\} = \frac{k_B}{\sqrt{\nu_e k^2}} \left[ D \left( \frac{\omega}{\sqrt{2} k_B \nu_e} + \frac{k}{\sqrt{2} k_B} \right) - D \left( \frac{\omega}{\sqrt{2} k_B \nu_e} - \frac{k}{\sqrt{2} k_B} \right) \right] \quad (3.6) \]

\[ \mathcal{R}\{e^{\text{in}}(k,\omega)\} = 1 - \frac{k_B n_e^0 \Phi_{e\text{e}}(k)}{\sqrt{2} m_e v_e^2 k} \left[ D \left( \frac{\omega}{\sqrt{2} k_B \nu_e} + \frac{k}{\sqrt{2} k_B} \right) - D \left( \frac{\omega}{\sqrt{2} k_B \nu_e} - \frac{k}{\sqrt{2} k_B} \right) \right] \quad (3.7) \]

\[ \mathcal{I}\{e^{\text{in}}(k,\omega)\} = \sqrt{\frac{\pi}{2}} k_B n_e^0 \Phi_{e\text{e}}(k) \frac{1}{m_e v_e^2 k} e^{-\frac{1}{2}} \left( \frac{\omega}{k_B \nu_e} \right)^2 e^{-\frac{1}{2}} \left( \frac{k}{k_B} \right)^2 \sinh \left( \frac{\omega}{k_B \nu_e} \right) \quad (3.8) \]

\[ \mathcal{R}\{G^{\text{cl}}(k,\omega)\} = \left( \frac{\omega}{k B \nu_e} \right)^2 e^{-\frac{1}{2}} \left( \frac{k}{k_B} \right)^2 \quad (3.9) \]
\[ \Im \{ \mathcal{G}^i(k, \omega) \} = \sqrt{2} \frac{\omega}{k v_e} \left[ 1 - \sqrt{2} \frac{\omega}{k v_e} D \left( \frac{\omega}{\sqrt{2} k v_e} \right) \right] \]  
(3.10)

\[ \Re \{ \epsilon^i(k, i\omega) \} = 1 - \frac{n_e^0 \Phi_{ee}(k)}{m_e v_e^2} \left[ 1 - \sqrt{2} \frac{\omega}{k v_e} D \left( \frac{\omega}{\sqrt{2} k v_e} \right) \right] \]  
(3.11)

\[ \Im \{ \epsilon^i(k, i\omega) \} = \sqrt{2} \frac{\pi^2}{m_e v_e^2} \frac{n_e^0 \Phi_{ee}(k)}{k v_e} e^{1/2} \left( \frac{\omega}{v_e} \right)^2 \]  
(3.12)

The interaction potentials \( \Phi_{ei}(k) \) and \( \Phi_{ee}(k) \) as Dawson’s Integral \( D(x) \) are given by

\[
\Phi_{ei}(k) = \frac{Ze^2}{\epsilon_0 k^2}, \quad \Phi_{ee}(k) = -\frac{e^2}{\epsilon_0 k^2}, \quad D(x) = e^{-x^2} \int_0^x dt \, e^{t^2}.
\]

We normalize the wavenumber and the frequency according to

\[ k \rightarrow k/k_D = k \lambda_D = k v_e/\omega_p \, , \, \omega_0 \rightarrow \omega_0/\omega_p \, , \, \omega^2 = n_e^0 e^2/\epsilon_0 m_e \, , \, v_{os} = \omega_0 v_{os} \]

and multiply by the ion density \( n_i^0 = n_0^i/Z \) (quasi neutrality). Because of the comparison to the literature the function \( G \) is substituted by \( \Xi = \sqrt{\frac{\pi}{2}} G(k, \omega \omega) \). The cycle-averaged absorbed energy density is then given by

\[
\overline{\epsilon_{\text{RPA}}} = -\frac{Z m_e \omega_p^4 \omega_0^3}{\pi^2 v_{os}} \int_0^\infty \frac{dk}{k} \sum_{l=1}^\infty \Re \left\{ \Xi(k, l\omega_0) \right\} \int_0^{kv_{os}} d\xi \, j_l^2(\xi). \]  
(3.13)

The classical and the quantum kinetic expressions only differ by the functions \( \epsilon(k, i\omega) \) and \( \Xi(k, \omega) \).

### 3.1.1 The long-wavelength approximation (LWA) and a remark on the literature

In the literature the term \( \Xi(k, \omega) \) in Eq. (3.13) generally does not occur. The reason for this is that the current density is treated in dipole approximation, the same as the so-called ‘straight orbit assumption’, which can be done in the LWA limit \( k \rightarrow 0 \). In detail this occurs in our framework if we set \( r_e = (t - \tau) p_e/m_e \) in Eq. (3.1). In the work of Hazak et al. [11] the corresponding term also appears and is treated in the LWA limit, that is in our notation \( \Xi \approx -i \) for \( k \ll 1 \). Figure 3.1(a) shows the real and imaginary part of \( \Xi(k, \omega) \). We realize that the LWA limit is fulfilled only up to \( k \approx 0.2 \), which is a very narrow region. So, this approximation seems to be poor. Nevertheless, what we are really looking for is a good approximation for the numerator of

\[
\Re \left\{ \Xi \right\} = \frac{\Re(\Xi) \Re(\epsilon) + \Im(\Xi) \Im(\epsilon)}{\Re^2(\epsilon) + \Im^2(\epsilon)} = -\frac{\Gamma(k, \omega)}{\Re^2(\epsilon) + \Im^2(\epsilon)}.
\]
Figure 3.1: a) The real and imaginary parts of the function $\Xi(k,\omega)$ for $\omega = \omega_p$ and $k_B = k_D$; the LWA limit $\Im \Xi = -1$ is reached at $k = 0$. b) The imaginary part of the dielectric function $\epsilon(k, i\omega)$ as well as the function $\Gamma(k, \omega)$ also for $\omega = \omega_p$ and $k_B = k_D$.

Looking at Fig. 3.1(b) we recognize that the numerator $\Gamma(k, \omega)$ is best approximated by the imaginary part of the dielectric function $\Im \epsilon(k, i\omega)$ and this reproduces the results from the literature. But, the current density as the time-dependent absorption is not well approximated by the LWA limit.

We close this section with our final expression for the cycle-averaged absorbed energy density:

$$\overline{\mathcal{E}}_{\text{RPA}} = \frac{Z m_{e} \omega_{p}^{4} \omega_{0}^{2}}{\pi^{2} v_{\text{os}}} \int_{0}^{\infty} \frac{dk}{k} \sum_{l=1}^{\infty} \frac{\Im \epsilon(k, il \omega_{0})}{|\epsilon(k, il \omega_{0})|^{2}} \int_{0}^{\frac{\hbar v_{\text{os}}}{e \omega_{0}}} d\xi J_{l}^{2}(\xi) . \tag{3.14}$$
3.2 The ballistic treatment

This model is based on a work of P. Mulser [16]. The impressive simplicity of this model leads to analytical expressions for the time-dependent collision frequency in an immediate way which where missing in the literature so far.

The collision frequency is calculated on the basis of a ballistic interaction model. Using the electron-ion scattering cross section the two-body interaction between one electron and one test ion is treated to all orders. The collision is treated as an instantaneous event not including the external field of the laser. The collective interaction of the electron is not calculated self-consistently, it is suggested by a screening length only.

![Diagram](image)

Figure 3.2: Isotropic electron distribution $f(v_e)$. The resultant velocities $v = v_{os} + v_e$ consist of all types of vectors $v_i, v'_i$ indicated in the Figure for two oscillation velocities $v_{os}(t)$ and $v_{os}(t')$. The momentum losses $\dot{p}$ form the angles $\alpha$ with $v_{os}$; the average loss $\langle \dot{p} \rangle$ is directed along $v_{os}$.

One electron of the statistical ensemble possesses the velocity $v(t) = v_{os}(t) + v_e$. During one collision with an ion of charge $Ze$ the electron is deflected by an angle $\vartheta$. The momentum change in direction of $v$ is $\Delta p_{\vartheta} = v(1 - \cos \vartheta)$. The differential cross section $\sigma_{\Omega}$ and the impact parameter for perpendicular deflection are given by

$$
\sigma_{\Omega} = \frac{b^2}{4 \sin^4 \frac{\vartheta}{2}}, \quad b_\perp = \frac{Ze^2}{4 \pi \varepsilon_0 m_e v^2} = \frac{7}{E[eV]} [\text{Å}], \quad \tan \frac{\vartheta}{2} = \frac{b_\perp}{b}.
$$

Integration of $\Delta p_{\vartheta}$ over the total cross section $\sigma = \pi b_{\text{max}}^2$ results in

$$
\Delta p = m_e v \frac{b_\perp^2}{\sigma} \int_{\vartheta=\vartheta}^{\pi-\vartheta} \frac{(1 - \cos \vartheta) \sin \vartheta}{4 \sin^4 \frac{\vartheta}{2}} d\vartheta d\varphi
\quad = 4 \pi m_e v \frac{b_\perp^2}{\sigma} \int_{b_{\text{min}}}^{b_{\text{max}}} \frac{1}{1 + \left(\frac{b_\perp}{b}\right)^2} db
\quad = 4 \pi m_e v \frac{b_\perp^2}{\sigma} \left[ \frac{b_{\text{max}}^2 + b_\perp^2}{b_{\text{min}}^2 + b_\perp^2} \right].
$$

(3.15)

(3.16)
\[ 4\pi m_e v \frac{b^2}{\sigma} \ln \Lambda. \]

In \( \Lambda \) denotes the so called Coulomb Logarithm. The lengths \( b_{\text{max}} \) and \( b_{\text{min}} \) herein are identified by the the screening length and the De Broglie wavelength. The upper cut-off \( b_{\text{max}} \) is necessary to avoid a logarithmic divergency for large \( b \). In Sections 3.3.2 and 3.3.4 these lengths will be analyzed based on the kinetic treatment.

Notice that the collision parameter \( b_{\perp} \) for perpendicular deflection is an inherent quantity for the Coulomb collision and not a cut-off.

The momentum loss per unit time is
\[ \dot{p} = \sigma n_i |v| \Delta p, \]
\[ \dot{p} = -m_e \nu_e(v) v = -\frac{K}{v^3} v, \quad K = \frac{Z^2 e^4 n_i}{4\pi \varepsilon_0^2 m_e \ln \Lambda}. \]

By the first equation the collision frequency \( \nu_e(v) \) is defined. To obtain the ensemble average of the momentum loss \( \langle \dot{p} \rangle \) we have to average \( v/v^3 \) over the thermal velocities \( v_e \). An isotropic electron distribution function is assumed \( f(v_e) \). The velocity \( v \) consists of all vector sums as sketched in Fig. 3.2. The momentum loss \( \dot{p} \) is parallel to \( v \), whereas the ensemble average points along \( v_{\text{os}} \). Determining the average of \( v/v^3 \) is perfectly analogous to calculating the gravitational force of a spherical mass distribution on a point mass at distance \( R \) from its center. The Coulomb Logarithm is treated as a constant during the average. We obtain
\[ \langle \dot{p} \rangle = m_e \nu_e(t) v_{\text{os}} = K \frac{v_{\text{os}}}{v_{\text{os}}} \int_0^{v_{\text{os}}} 4\pi v_e^2 f(v_e) dv_e. \]

The time-dependent collision frequency of the ensemble is defined by \( \nu_e(t) = \nu_e(t) v_{\text{os}} \) and results in
\[ \nu_e(t) = \frac{K}{m_e v_{\text{os}}^3(t)} \int_0^{v_{\text{os}}} 4\pi v_e^2 f(v_e) dv_e. \]

Taking a Maxwell distribution
\[ f_M = \left( \frac{2\pi v_e^2}{\varepsilon_0^2} \right)^{-3/2} e^{-v_e^2/2\varepsilon_0^2}, \]
we obtain
\[ \nu_e(t) = \frac{K}{m_e v_{\text{os}}^3(t)} \left[ \text{erf} \left( \frac{v_{\text{os}}(t)}{\sqrt{2}\varepsilon_0} \right) - 2 \frac{v_{\text{os}}(t)}{\sqrt{2}\varepsilon_0} e^{-\frac{v_{\text{os}}^2(t)}{2\varepsilon_0^2}} \right]. \]

The energy absorption is related to the time averaged collision frequency by
\[ m_e \nu_e v_{\text{os}}^2 = m_e \nu_e v_{\text{os}}^2 = 2\nu_e \bar{E}_{\text{kin}}. \]

Thus, for the time averaged energy absorption density we find
\[ \bar{\mathcal{E}} = 2m_e \nu_e \bar{E}_{\text{kin}} = Z \omega_0^4 m_e \ln \Lambda \frac{1}{\nu_e(t)} \int_0^{v_{\text{os}}(t)} v_e^2 f_M(v_e) dv_e. \]
3.3 A combined model for collisional absorption

The kinetic calculation of the absorption done in Sec. 3.1 includes screening and quantum effects in a self-consistent manner, but it is limited to first order in the electron-ion interaction. In contrast, in the ballistic model the electron-ion collisions are calculated exactly in each order of the interaction, but cut-offs have to be introduced from outside to incorporate screening and quantum effects. In the following sections we shall join both treatments to get a combined model, avoiding in this way the inherent approximations: i) first order electron-ion interaction only, ii) the artificial introduction of cut-offs. (See also the discussion in Sec. 2.1.4.)

3.3.1 The connection between the kinetic and the ballistic treatment

In the following the symbol \( \nu_{\text{th}} \) denotes the thermal velocity of the electrons and \( \hat{v}_{\text{os}} \) the amplitude of the electron oscillation velocity. The wavenumber \( k \) is normalized to \( k_D = \lambda_D^{-1} \), the inverse thermal Debye length, and the laser frequency \( \omega_0 \) is normalized to the plasma frequency \( \omega_p \).

From the kinetic treatment of the absorption we found, Eq. (3.14),

\[
\frac{\dot{E}_{\text{RPA}}}{\omega_p} = \frac{Z m_e \omega_p^4}{\pi^2 \hat{v}_{\text{os}}} \int_0^\infty \frac{dk}{k} F \left( k, \omega_0 \hat{v}_{\text{os}} \nu_{\text{th}} \right)
\]  

(3.21)

with the integral kernel

\[
F \left( k, \omega_0 \hat{v}_{\text{os}} \nu_{\text{th}} \right) = \omega_0^2 \sum_{l=1}^\infty \frac{\Im \epsilon(k, il\omega_0)}{\epsilon(k, il\omega_0) |\epsilon(k, il\omega_0)|^2} \int_0^{\hat{v}_{\text{os}} \omega_0 \nu_{\text{th}}} \xi J_l^2(\xi) \ .
\]  

(3.22)

From the ballistic treatment we got Eq. (3.20),

\[
\frac{\dot{E}_{\text{ball}}}{\omega_p} = \frac{Z m_e \omega_p^4}{\pi^2 \hat{v}_{\text{os}}} \ln \Lambda G \left( \hat{v}_{\text{os}} \nu_{\text{th}} \right)
\]  

(3.23)

\[
\ln \Lambda = \frac{1}{2} \ln \left( \frac{b_{\text{max}}^2 + b_{\text{min}}^2}{b_{\text{max}}^2 + b_{\perp}^2} \right)
\]

where we have introduced the abbreviation

\[
G \left( \hat{v}_{\text{os}} \nu_{\text{th}} \right) = \pi^2 \hat{v}_{\text{os}} \int_0^{\nu_{\text{os}}(t)} \frac{v_{\text{e}}^2 f_M(v_{\text{e}}) dv_{\text{e}}}{\nu_{\text{os}}(t)}
\]  

(3.24)

For the moment, setting the dielectric function \( \epsilon = \epsilon^\text{cl} \), Eqs. (3.11) and (3.12), we restrict the function \( F \) to the classical regime. The inclusion of quantum effects will follow in Sec. 3.3.4.

The integral kernel \( F \) is a very complicated function. It is difficult to obtain analytically \( F \).
in dependence of $k$ and $v_{os}/v_{th}$. Therefore, in Fig. 3.3 $F$ is plotted numerically over $k$ for a wide range of $v_{os}$, namely $1 \leq v_{os}/v_{th} \leq 6$. The ratio $\omega_0/\omega_p$ is set equal to 2. Now, when evaluating numerically $G$ the most remarkable result is obtained that, latest from $k/k_D = 3$ the function $G$ represents an excellent approximation of $F$, as seen from Fig. 3.3. From the numerical analysis we deduce the asymptotic equivalence

$$\lim_{k \to \infty} F\left(k, \frac{\omega_0}{\omega_p}, \frac{v_{os}}{v_{th}}\right) = G\left(\frac{v_{os}}{v_{th}}\right)$$

which connects the kinetic absorption rate Eq. (3.21) and the absorption rate calculated by the ballistic model Eq. (3.23).

This asymptotic equivalence is the salient point of the present work. It is the foundation for further analytical simplifications of the absorption rate which otherwise are very hard to achieve. In fact, as we shall see in a moment, it introduces the concept of the Coulomb Logarithm into the kinetic treatment, and by choosing the latter appropriately the equiva-
The fact, that the integral kernel $F$ becomes constant for large wavenumbers, leads, in the classical case, to the well known logarithmic divergence in Eq. (3.21). This divergence occurs because of the first order Born approximation which only describes weak collisions correctly. The inclusion of strong binary collisions, Sec. 3.3.3, as well as quantum effects, Sec. 3.3.4, will remove this divergence. It is standard to avoid the divergence by replacing the upper limit of the integral with an upper cut-off $k_{\text{max}}$.

The decomposition of the function $F$ into a product of a rectangular Theta-function $\Theta(k - k_{\text{min}})$ and the function $G$ in such a way that the areas in Fig. 3.3 become equal immediately leads to the Coulomb Logarithm $\ln \Lambda$ of the ballistic model, Eq. (3.23), when set $b_\perp = 0$ (first order Born approximation):

$$
\int_0^{k_{\text{max}}} \frac{dk}{k} F\left(k, \omega_0, \frac{\hat{v}_{\text{os}}}{v_{\text{th}}} \right) = \int_0^{k_{\text{max}}} \frac{dk}{k} G\left( \frac{\hat{v}_{\text{os}}}{v_{\text{th}}} \right) \Theta(k - k_{\text{min}})
$$

$$
= G\left( \frac{\hat{v}_{\text{os}}}{v_{\text{th}}} \right) \ln \frac{k_{\text{max}}}{k_{\text{min}}} = G\left( \frac{\hat{v}_{\text{os}}}{v_{\text{th}}} \right) \ln \frac{b_{\text{max}}}{b_{\text{min}}} \quad (3.26)
$$

$$
\ln \Lambda = \ln \frac{b_{\text{max}}}{b_{\text{min}}}. 
$$

The lower cut-off $k_{\text{min}} = b_{\text{max}}^{-1}$ is identified with the inverse screening length of the ion potential. In the ballistic model this length is introduced from outside. By the above equations we are able to determine the screening length self-consistently which is done in the next section.

### 3.3.2 The screening length

For small wavenumbers the asymptotic equality Eq. (3.25) is not fulfilled. The kinetic integral kernel $F$ decreases for $k < 4k_D$ because of the screening of the ion potential by the electrons, see Fig. 3.3. For a plasma in thermal equilibrium the effective screening length is given by the Debye length $\lambda_D = k_D^{-1} = v_{\text{th}}/\omega_p$. Now, in the presence of a strong laser field due to the electron oscillation the screening length is expected to contain a dynamical part which should scale as $\hat{v}_{\text{os}}/\max(\omega_0, \omega_p)$ [15].

This dynamical screening length is the inverse $k_{\text{min}}$ introduced in the previous section. It is determined self-consistently by comparing the integrals

$$
\int_0^{k_0} \frac{dk}{k} F\left(k, \omega_0, \frac{\hat{v}_{\text{os}}}{v_{\text{th}}} \right) = \int_0^{k_0} \frac{dk}{k} G\left( \frac{\hat{v}_{\text{os}}}{v_{\text{th}}} \right) \Theta(k - k_{\text{min}}).
$$

Whatever the value of $k_0$ is, as long as $k_0$ is in the range of the asymptotic, $F(k_0) = G$, the inverse screening length $k_{\text{min}}$ does not depend on $k_0$.

The kinetic inverse screening length becomes

$$
k_{\text{min}} = k_0 \exp\left(-\int_0^{k_0} \frac{dk}{k} F\right) \cdot (3.27)
$$
Figure 3.4: The inverse screening length $k_{\text{min}}$ (solid, eq. (3.27)) and the approximation (dashed, Eq. (3.28)) as a function of the electron oscillation velocity over the electron thermal velocity $\hat{v}_{\text{os}}/v_{\text{th}}$ (top) and as a function of the laser frequency over the plasma frequency $\omega_0/\omega_p$ (bottom).
In Fig. 3.4 $k_{\text{min}}$ is plotted over $\hat{v}_{\text{os}}/v_{\text{th}}$ and $\omega_0/\omega_p$ (solid lines). As a rough approximation for $k_{\text{min}}$, similar to [16], we choose

$$k_{\text{min}} \approx \left( \frac{\sqrt{\hat{v}_{\text{os}}^2/4 + v_{\text{th}}^2}}{\max(\omega_0, \omega_p)} \right)^{-1}$$

(3.28)

which ensures the expected asymptotic behavior as one of the four quantities goes to zero. The expression is also plotted in Fig. 3.4 (dashed lines). In contrast to [16] in the above expression for $k_{\text{min}}$ the oscillation term is changed empirically from $\hat{v}_{\text{os}}^2/2$ to $\hat{v}_{\text{os}}^2/4$ since this leads to a better agreement.

A so far unknown behavior of the dynamical screening length appears in the upper of Figs. 3.4: the exact inverse screening length $k_{\text{min}}^{-1}$ saturates for large oscillation velocities (solid lines) in contrast to a decrease proportional to $\hat{v}_{\text{os}}^{-1}$ which is expected from the literature. This feature is not understood so far; however, an explanation is in progress. The $\omega_0/\omega_p$ dependence is qualitatively as expected. Beside the saturation for large $\hat{v}_{\text{os}}$ the approximation, Eq. (3.28), works quite well. Last but not least, because $k_{\text{min}}^{-1}$ enters only logarithmically in the absorption rate the deviations are reduced.

### 3.3.3 Strong two-body collisions

As mentioned in the beginning of this section, our kinetic approach is not able to handle strong two-body collisions because of the first order Born approximation. However, the ballistic treatment is able. To include strong two-body collisions in the kinetic treatment one has to calculate, in addition to the RPA-diagrams (Eq. (2.12)), the infinite series of ladder-diagrams, Eq. (2.8). Nevertheless, also for this simplified approach a complete analytical solution is not accessible because of the time varying electric field of the laser. The kinetic model includes the laser field exactly for the weak collisions. During a strong two-body collision the Coulomb force dominates the interaction with the electric field of the laser. Therefore, it is sufficient to take account for the electric field in the velocity of the impinging electron as done by the ballistic model.

Let us rewrite the absorption rate from the ballistic model, Eq. (3.23), using the integral notation for the Coulomb Logarithm, Eq. (3.16). Therein $b_{\text{min}}$ is set zero because it is an artificial cut-off which is not part of the kinetic treatment:

$$\frac{\mathcal{E}_{\text{ball}}}{\mathcal{E}_{\text{RPA}}} = \frac{Z m_e \omega_p^4}{\pi^2 \hat{v}_{\text{os}}^4} G \left( \frac{\hat{v}_{\text{os}}}{v_{\text{th}}} \right) \int_0^{b_{\text{max}}} \frac{1}{1 + \left( \frac{b}{b_{\text{min}}} \right)^2} \frac{db}{b} \bigg|_k = b^{-1}$$

$$= \frac{Z m_e \omega_p^4}{\pi^2 \hat{v}_{\text{os}}^4} G \left( \frac{\hat{v}_{\text{os}}}{v_{\text{th}}} \right) \int_{k_{\text{min}}}^{\infty} \frac{dk}{1 + (kb_{\perp})^2}$$

Using the results from Sections 3.3.1 and 3.3.2 the kinetic absorption rate becomes

$$\frac{\mathcal{E}_{\text{RPA}}}{\mathcal{E}_{\text{RPA}}} = \frac{Z m_e \omega_p^4}{\pi^2 \hat{v}_{\text{os}}^4} \int_0^{\infty} \frac{dk}{k} \frac{F \left( k, \omega_0, \frac{\hat{v}_{\text{os}}}{v_{\text{th}}} \right)}{k}$$
Comparing the above integrals inside the ballistic and the kinetic expressions we observe the additional factor \( (1 + (kb^\perp)^2)^{-1} \) in the ballistic case, which is the only difference. This factor has its seeds in the strong two-body collisions; if we take the limit \( b^\perp \to 0 \) we recover the first order Born approximation. As outlined above the ballistic and the classical dielectric model coincide for weakly bent orbits if the Coulomb logarithm is defined properly. Furthermore, in the ballistic model the contribution of the strongly bent orbits is correctly included if the interaction is an unshielded Coulomb potential, or, in other words, when \( b^\perp \ll \lambda_D \). Since these orbits are also solutions of the Vlasov equation when \( b^\perp \ll \lambda_D \) we have proofed that the kinetic integral, Eq. (3.21), is to be regularized by \( b^\perp \) in order to treat close encounters. The absorption rate from this combined approach takes the form

\[
\dot{E} = \frac{Zm_e\omega_p^4}{\pi^2\hat{v}_{os}} G(\hat{v}_{os}/v_{th}) \int_{k_{min}}^{\infty} \frac{dk}{k} \int_{k_{min}}^{\infty} \frac{dk}{k} \frac{1}{k^2} F(\hat{v}_{os}, \hat{v}_{os}/v_{th}).
\]  

(3.29)

### 3.3.4 Inclusion of quantum effects

The choice of the quantum kinetic dielectric function, Eq. (3.7) and Eq. (3.8), within the integral kernel \( F \), Eq. (3.21), leads to the quantum kinetic expression for the absorption. The major differences to the classical integral kernel appear in the numerator of \( F \) due to the imaginary part of the dielectric function. The quantum expression contains a Gaussian decrease for large ratios \( k/k_B \) as well as a sinh-dependency of the frequency. At first glance, it seems to be surprising that only the thermal De Broglie wavenumber appears, which we defined in Appendix B as \( k_B = (\hbar/2m_e v_{th})^{-1} \). We would expect that due to the oscillatory motion of the electrons also a term depending on the oscillation velocity should occur. And indeed, the physical intuition is right! The numerical analysis of \( F \) shows that the oscillation velocity enters the De Broglie wavenumber due to the sinh-term inside the imaginary part of the quantum kinetic dielectric function, \( \sinh(\omega_0 k_{B}/v_{th}) \). This term rescales the De Broglie wavenumber by an average velocity of about \( \sqrt{\hat{v}_{os}^2/4 + v_{th}^2} \). Analytically the meaning of this term is not obvious because it does not depend on \( \hat{v}_{os} \). The only coupling to \( \hat{v}_{os} \) occurs according to the summation over the integrals of Bessel functions where \( \hat{v}_{os} \) appears in the upper limit of the integrals. The numerical analysis shows that neglecting the sinh-term only the thermal De Broglie wavenumber occurs.

In Fig. 3.5 the full quantum kinetic kernel

\[
F_{qu}(k, \omega_0, \hat{v}_{os}/v_{th}) = \omega_0^2 \sum_{l=1}^{\infty} l \frac{\Im e^{ml}(k, il\omega_0)}{\left|e^{ml}(k, il\omega_0)\right|^2} \int_0^{k_{min}/v_{th}} \int_0^{k_{min}/v_{th}} d\xi J_l^2(\xi),
\]  

(3.30)

the classical one

\[
F_{cl}(k, \omega_0, \hat{v}_{os}/v_{th}) = \omega_0^2 \sum_{l=1}^{\infty} l \frac{\Im e^{ml}(k, il\omega_0)}{\left|e^{ml}(k, il\omega_0)\right|^2} \int_0^{k_{min}/v_{th}} \int_0^{k_{min}/v_{th}} d\xi J_l^2(\xi)
\]  

(3.31)
and the approximation

\[ F_{av}(k, \omega_0, \hat{v}_{os}) = e^{-\frac{1}{2}\left(\frac{k}{\langle k_B \rangle}\right)^2} F_{cl}(k, \omega_0, \hat{v}_{os}) \]  

are compared to each other. In the latter we have introduced the mean De Broglie wavenumber

\[ \langle k_B \rangle = \left(\frac{\hbar}{2m_e \sqrt{\hat{v}_{os}^2/4 + v_{th}^2}}\right)^{-1}. \]

The approximation is quite well fulfilled for the whole parameter region. This is a very useful result and makes analytic approximations for the absorption quite easy. Note that only taking into account the thermal De Broglie wavenumber \( F = F_{th} \) and neglecting the discussed sinh-term, underestimates the integral kernel for \( v_{os} > v_{th} \), Fig. 3.5 c) and d).

Figure 3.5: Plot of the integral kernel, Eq. (3.22), in the classical case \( F_{cl} \), in the quantum regime \( F_{qu} \), the approximation \( F_{av} \), and the approximation \( F_{th} \) which contains the thermal De Broglie wavenumber only; \( \omega_0 = 2\omega_p \); a) \( k_B = k_D, \, \hat{v}_{os} = v_{th} \); b) \( k_B = 8k_D, \, \hat{v}_{os} = v_{th} \); c) \( k_B = k_D, \, \hat{v}_{os} = 6v_{th} \); d) \( k_B = 8k_D, \, \hat{v}_{os} = 6v_{th} \). In all cases \( F_{av} \) agrees well with the correct expression \( F_{qu} \) when \( \langle k_B \rangle \) is chosen as indicated by Eq. (3.33).
3.3.5 The combined absorption result

The combination of the results Eq. (3.29) and Eq. (3.32) leads us to the expression

$$\dot{\mathcal{E}} = Z m_e \omega_p^4 \int_0^\infty \frac{dk}{k} e^{-\frac{1}{2}\left(\frac{k}{\langle k_B \rangle}\right)^2} \frac{4 \pi}{1 + (kb_{\perp})^2} F_{cl}(k, \omega, \hat{v}_{os}, v_{th}) .$$

Again we use the asymptotic congruence of the ballistic with the kinetic model, Eq. (3.25), and write the $k$-dependence of the function $F_{cl}$ as a theta function $\Theta(k - k_{\text{in}})$ where the inverse dynamical screening length $k_{\text{in}}$ is determined by Eq. (3.27). The resultant $k$-integral

$$\ln \Lambda_G = \int_{k_{\text{in}}}^\infty \frac{dk}{k} e^{-\frac{1}{2}\left(\frac{k}{\langle k_B \rangle}\right)^2}$$

is solvable [20] and defines a generalized Coulomb Logarithm $\ln \Lambda_G$ expressed by a difference of exponential-integrals of the first kind $[\lambda_B = \langle k_B \rangle^{-1}, b_{\text{max}} = k_{\text{in}}^{-1}]$:

$$\ln \Lambda_G = \frac{1}{2} \left[ E_1 \left( \frac{1}{2} \left( \frac{\lambda_B}{b_{\text{max}}} \right)^2 \right) - e^{\frac{1}{2}\left(\frac{\pi B}{\lambda_B}\right)^2} E_1 \left( \frac{1}{2} \left( \frac{\lambda_B}{b_{\text{max}}} \right)^2 + \frac{1}{2} \left( \frac{\lambda_B}{b_{\perp}} \right)^2 \right) \right] .$$

(3.34)

This Coulomb Logarithm does never become negative, in contrast to the standard expression of $\ln \Lambda$ from Eq. (3.26), since the integrand is always positive. The problem of a negative Coulomb Logarithm, often noticed in the literature, does not occur.

For the time averaged absorption rate we end up with

$$\overline{\dot{\mathcal{E}}} = Z m_e \omega_p^4 \ln \Lambda_G \frac{1}{v_{os}(t)} \int_0^{v_{os}(t)} v_{e}^2 f_M(v_e) \ dv_e .$$

(3.35)

For the velocity dependence of the parameter for perpendicular deflection $b_{\perp}$, Eq. (3.15), we use the $v_{os}^2/4 + v_{th}^2$ term by analogy to the velocity dependence of the average De Broglie length. From the ballistic model, Eq. (3.18) and Eq. (3.19), we get the cycle-averaged function in Eq. (3.35):

$$\frac{1}{v_{os}(t)} \int_0^{v_{os}(t)} v_{e}^2 f_M(v_e) \ dv_e = \omega_0 \int_0^{\omega_0} \frac{dt}{2\pi} \left[ \text{erf} \left( \frac{v_{os}(t)}{\sqrt{2}v_{th}} \right) - \frac{2}{\sqrt{\pi}} \frac{v_{os}(t)}{\sqrt{2}v_{th}} e^{-\frac{v_{os}(t)^2}{2v_{th}}} \right] .$$

(3.36)

The numerical evaluation of this integral is quite simple. The result is shown in Fig. 3.6.

To confirm the correctness of the preceding analysis we look at the limit of the above generalized Coulomb Logarithm for a high energy plasma, that is, for small $\lambda_B$ and $b_{\perp}$. Using for $E_1$ the expansion [21]

$$E_1(x) = -\gamma - \ln x - \sum_{n=1}^{\infty} \frac{(-1)^n x^n}{n n!} \quad \gamma = 0.5772156649\ldots \text{ is Euler’s constant},$$

...
we find, in complete agreement to the ballistic model, the usual Coulomb Logarithm, Eq. (3.16), for $b_{\text{min}} = \lambda_B \to 0$:

$$
\ln \Lambda_G \equiv 2 \ln \left( 1 + \frac{b_{\text{max}}^2}{b_{\perp}^2} \right).
$$

If $b_\perp$ shrinks to zero we can use the relation [22]

$$
\frac{1}{2} \ln \left( 1 + \frac{2}{x} \right) < e^{x} E_1(x) < \ln \left( 1 + \frac{1}{x} \right) \quad (x > 0)
$$

which leads to

$$
\ln \Lambda_G \equiv 2 E_1 \left( \frac{1}{2} \left( \frac{\lambda_B}{b_{\text{max}}} \right)^2 \right) \approx \ln \left( \sqrt{2} \frac{b_{\text{max}}}{\lambda_B} \right) - \gamma^2.
$$

The latter limit for $\lambda_B \ll b_{\text{max}}$ is in agreement with results of Kull and Plagne [10].
Chapter 4

Results and Conclusion

For the comparison with the literature we relate the absorbed energy density rate to the electron-ion collision frequency according to the standard expression

$$\nu_{ei} = \frac{2\overline{\dot{E}}}{2n_e E_{\text{kin}}} = \frac{2\overline{\dot{E}}}{m_e n_e \overline{v_{os}}^2}$$

from the Drude model.

In Figure 4.1 the full quantum kinetic electron-ion collision frequency with and without inclusion of strong binary collisions is compared to the approximations given by the combined model. The full quantum solution is calculated only up to $\overline{v_{os}}/v_{th} = 10$ because of the large numerical effort involved; the numerical integration range in Eq. (3.29) is up to $k/k_D = 150$ and one has to add up about 500 Bessel functions for large values of $k/k_D$.

We have chosen the same parameters as shown by Bornath et al. [13, Fig. 1, 2]. Their results match exactly our ones in the case $b_\perp = 0$. Nevertheless, including strong binary collisions, that is $b_\perp \neq 0$, leads to a decrease in the collision frequency. This tendency is in agreement with the results of Gericke and Schlanges [19]. Including numerically the static T-Matrix - the sum of all ladder graphs - in the stopping power calculation of an ion-beam, they also find a decrease in the stopping power compared to the first order Born result. The approximation which takes into account the kinetic screening length, Eq. (3.35), is very successful. It becomes exact for values $\overline{v_{os}}/v_{th} > 3$. Using for the screening length the rough estimate Eq. (3.28) the approximation for the collision frequency fails for $\overline{v_{os}}/v_{th} < 4$ [Fig. 4.1, dotted line].

By the additional scale of $b_\perp$ the collision frequency also changes its density dependence, as seen in Fig. 4.2. Due to the strong binary collisions the maximum of the electron-ion collision frequency is strongly shifted and reduced. At large densities the approximation Eq. (3.35) no longer fits the exact result. That is, because with increasing density the ratios $\lambda_B/\lambda_D$ as well as $b_\perp/\lambda_D$ become larger and one would have had to take into account these scales when calculating the screening length. In the upper of Fig. 4.2 the ratios take the values: $\lambda_B/\lambda_D = 0.007$ $b_\perp/\lambda_D = 0.012$ for $n_e = 10^{26}$ m$^{-3}$; $\lambda_B/\lambda_D = 0.227$ $b_\perp/\lambda_D = 0.373$ for $n_e = 10^{29}$ m$^{-3}$. The deviation becomes smaller with increasing $\overline{v_{os}}$ and thus decreasing $b_\perp$, as seen from the lower of Fig. 4.2.
According to the $Z$ dependency of $b_\perp$ the collision frequency no longer depends linearly on the ion charge number, see Fig. 4.3. For the given values of $\hat{v}_{os}/v_{th} = 1.0(2.0)$ and $\omega_0/\omega_p = 5$ the collision frequency for $Z = 1$ scales as $\nu_{ei} \sim Z^{0.2}(Z^{0.4})$. At $Z = 10$ this scaling changes to $\nu_{ei} \sim Z^{-0.8}(Z^{-0.6})$. For larger energies at decreasing $b_\perp$ the exponent will become 1. Again, this behavior according to the charge number $Z$ is in agreement with the results of Gericke and Schlanges [19].

Figure 4.1: Electron-ion collision frequency as a function of the oscillation velocity $\hat{v}_{os}$; $Z = 1, n_e = 10^{28} \text{ m}^{-3}, T_e = 3 \cdot 10^5 \text{ K} = 25.85 \text{ eV}, \omega_0/\omega_p = 5$. The full quantum solution, Eq. (3.29), with and without $b_\perp$; the approximation, Eq. (3.35), with the self-consistent screening length and with the ballistic one, Eq. (3.28); upper: logarithmic scale, lower: linear scale. The approximation including the self-consistent kinetic screening length (dashed line) fits best the full quantum kinetic solution (solid line).
Figure 4.2: Electron-ion collision frequency as a function of the density; $Z = 1$, $T_e = 3 \cdot 10^5$ K = 25.85 eV, $\omega_0/\omega_p = 5$. upper: $\hat{v}_{os}/v_{th} = 1$, lower: $\hat{v}_{os}/v_{th} = 2$. The best approximation to the full quantum kinetic solution (solid line) is the one including the self-consistent kinetic screening length (dashed line). This approximation fails for $\hat{v}_{os}/v_{th} \leq 1$ and $n_e \geq 3 \cdot 10^{28} \text{m}^{-3}$ (upper figure), because the relations $\lambda_{B}/\lambda_{D}$ and $b_{\perp}/\lambda_{D}$ are no longer much smaller than one; $\lambda_{B}/\lambda_{D} = 0.227$, $b_{\perp}/\lambda_{D} = 0.373$ for $n_e = 10^{29} \text{m}^{-3}$. 
Figure 4.3: Electron-ion collision frequency normalized by $Z$ as a function of the ion charge number $Z$; $n_e = 10^{28} \text{ m}^{-3}, T_e = 3 \cdot 10^5 \text{ K}, eV, \omega_0/\omega_p = 5$. upper: $\hat{v}_{os}/v_{th} = 1$, lower: $\hat{v}_{os}/v_{th} = 2$. According to the linear $Z$ dependence of $b_\perp$ the relation $\nu_{ei}/Z$ is no longer constant.
We can finish the present investigation with a short and concise summary of the main results:

- The impact of many-particle collisions was discussed. We came to the conclusion that in the mean, due to the velocity and density scaling of the screening length as well as the parameter of rectangular deflection, the influence of strong electron-ion many-body collisions is small. Most of these are weak collisions which can be calculated by first order Born approximation. Nevertheless, the inclusion of strong binary collisions is important.

- The quantum kinetic expression for the absorption rate in random phase approximation (RPA) was calculated. It was shown that in general the long-wavelength approximation (LWA) fails. Nevertheless, we could demonstrate that the result for the time averaged absorption rate calculated by using the LWA limit remains valid.

- With the help of the ballistic model the kinetic treatment in RPA, which is limited to weak collisions, could be extended analytically for the first time to the case of strong binary collisions. The result is a combined model which was, in particular cases, numerically achieved by others adding the static screened T-Matrix to the RPA results.

- The combination of the ballistic and the kinetic treatment led us to closed analytical expressions for the absorption rate. It bypasses the difficult summation and integration of a large amount of Bessel functions appearing in the kinetic treatment.

- A so far unknown saturation behavior of the screening length has been found: It becomes constant for large oscillation velocities. The interpretation of this effect in physical terms is in progress.
Appendix A

Explicit Expressions for Propagators

A.1 Free propagators

Due to the missing interaction of the particles the many-body propagator separates into 1-particle propagators:

\[ \prod_{i=1}^{N} \tau_i = \tau_1 \ldots \tau_N. \]

The most simple propagator describes the free movement of the particle with momentum \( \vec{p}_j \) acting as a shift operator:

\[ \tau_1 f(\vec{r}_1, \vec{p}_1) = e^{-\frac{\tau \vec{p}_1}{m_1}} \frac{\partial}{\partial \vec{r}_1} f(\vec{r}_1, \vec{p}_1) = f(\vec{r}_1 - \frac{\tau \vec{p}_1}{m_1}, \vec{p}_1). \]

\[ (\tau_1 f \tau_1^{-1}) = e^{+\frac{\tau \vec{p}_1}{m_1}} \]

\[ \tau_1 f g = [\tau_1 f, \tau_1 g]. \]

The expression for the propagator including a time but not position dependent field \( \vec{F} \) is given by a shift in position and, after that, a shift in momentum:

\[ L_1 = L_1^0 + L^{\text{ex}} \]

\[ \tau_1 = e^{-i \int \vec{L}_1} = e^{-i \int \left[ \tau_1^0 + \int L^{\text{ex}} \right]} \]

\[ e^{-i \int \vec{L}^{\text{ex}}} \int L_1^0 e^{-i \int \vec{L}^{\text{ex}}} = \frac{i}{m_1} \frac{\partial}{\partial \vec{r}_1} - i \vec{F} \cdot \frac{\partial}{\partial \vec{p}_1} - e^{i \int \vec{F} \cdot \frac{\partial}{\partial \vec{p}_1}} \]

\[ = -e^{i \int \vec{L}^{\text{ex}}} \int L_1^0 e^{-i \int \vec{L}^{\text{ex}}} \]

\[ = - \frac{1}{m_1} \left[ e^{i \int \vec{F} \cdot \frac{\partial}{\partial \vec{p}_1}} \frac{\partial}{\partial \vec{r}_1} e^{-\int \vec{F} \cdot \frac{\partial}{\partial \vec{p}_1}} \right]. \]
APPENDIX A. EXPLICIT EXPRESSIONS FOR PROPAGATORS

\[ = -\frac{1}{m_1} \left( \vec{p}_1 + \int F \right) \frac{\partial}{\partial \vec{r}_1} \]

\[ \Rightarrow \]

\[ \uparrow_1^\tau = e^{-\int F \frac{\partial}{\partial \vec{r}_1}} e^{-\frac{1}{m_1} (\tau \vec{p}_1 + \int \vec{F}) \frac{\partial}{\partial \vec{r}_1}} \]

\[ \downarrow_1^\tau = e^{\frac{1}{m_1} (\tau \vec{p}_1 + \int \vec{F}) \frac{\partial}{\partial \vec{r}_1}} e^{\int F \frac{\partial}{\partial \vec{p}_1}} \]

(A.1)

A.2 Propagators including first order pair interaction

We calculate the first order of the ladder-propagator (2.9). The 1-particle propagators \( (\uparrow_1^{\tau_1,\tau_2} = \uparrow_1^{\tau_1} \uparrow_2^{\tau_2}) \) could contain a time-dependent external field:

\[ \uparrow_1^{\tau_1} \sim \sim \uparrow_1^{\tau_1} \]

(A.2)

\[ \uparrow_1^{\tau_1} = \int_0^{\tau_1} \frac{\partial \Phi(1,2)}{\partial \vec{r}_1} \left( \frac{\partial}{\partial \vec{p}_1} - \frac{\partial}{\partial \vec{p}_2} \right) \uparrow_1^{\tau_1} \]

\[ \uparrow_1^{\tau_1} = \int_0^{\tau_1} \left[ \frac{\partial \Phi(1,2)}{\partial \vec{r}_1} \right] \left( \frac{\partial}{\partial \vec{p}_1} - \frac{\tau}{m_1} \frac{\partial}{\partial \vec{r}_1} + \frac{\tau}{m_2} \frac{\partial}{\partial \vec{r}_2} \right) \uparrow_1^{\tau_1} \]

Thinking on the Coulomb interaction and the external field of the laser in dipole approximation leads us to the potential term Fourier transformed with respect to the particle distance

\[ \uparrow_{12}^{\tau} \Phi(1,2) = \frac{q_1 q_2}{4\pi \epsilon_0} \int \frac{d^3 k}{(2\pi)^3} k^2 \ e^{i k} \left( \vec{r}_1 + \frac{\tau}{m_1} \vec{p}_1 - \frac{\tau}{m_2} \vec{p}_2 + \frac{\tau}{m_1} \frac{\vec{E}_0}{\omega_0} \right) \]

If the electric field oscillates periodically like \( E(t) = E_0 \cos \omega_0 t \), this term can be transformed into a Bessel sum \( (J_l \text{ Bessel function of order } l)\):

\[ \downarrow_{12}^{\tau} \Phi(1,2) = \frac{q_1 q_2}{4\pi \epsilon_0} \sum_{l=-\infty}^{l=\infty} (-1)^l e^{i l \omega_0 \tau} \]

\[ \int \frac{d^3 k}{(2\pi)^3} \ rac{1}{k^2} \ J_l \left( \frac{k}{m_1} \frac{q_1}{m_2} \frac{E_0}{\omega_0} \right) e^{i k} \left( \vec{r}_1 + \frac{\tau}{m_1} \vec{p}_1 - \frac{\tau}{m_2} \vec{p}_2 + \frac{\tau}{m_1} \frac{\vec{E}_0}{\omega_0} \right) \]
APPENDIX A. EXPLICIT EXPRESSIONS FOR PROPAGATORS

With regard to the RPA approximation we look at the operator (A.2) after the reduction of one particle. Again, we choose the Fourier representation with respect to the particle distance for the potential term:

\[
\int_0^{\tau'} \int_0 \int d^3 \vec{k} \Phi_{12}(k) \ e^{i k \left( \frac{\eta_1 - \eta_2}{m_1} \int \vec{E} - \vec{p}_2 - \frac{\tau}{m_2} \vec{p}_2 \right)}
\]

\[
\int d^3 \vec{r}_1 d^3 p_1 \ e^{i k (\vec{r}_1 + \frac{\tau}{m_1} \vec{p}_1)} \left( \frac{\partial}{\partial \vec{p}_1} - \frac{\tau}{m_1} \frac{\partial}{\partial \vec{r}_1} - \frac{\partial}{\partial \vec{p}_2} + \frac{\tau}{m_2} \frac{\partial}{\partial \vec{r}_2} \right) \int d^3 \vec{r}_1 d^3 p_1 \ e^{i k (\vec{r}_1 + \frac{\tau}{m_1} \vec{p}_1)}
\]

\[
= i \int_0^{\tau'} \int_0 \int d^3 \vec{k} \Phi_{12}(k) \ e^{i k \left( \frac{\eta_1 - \eta_2}{m_1} \int \vec{E} - \vec{p}_2 - \frac{\tau}{m_2} \vec{p}_2 \right)}
\]

\[
\left( \frac{\tau}{m_1} i k - \frac{\tau}{m_1} \frac{\partial}{\partial \vec{p}_1} + \frac{\tau}{m_2} \frac{\partial}{\partial \vec{r}_2} \right) \int d^3 \vec{r}_1 d^3 p_1 \ e^{i k (\vec{r}_1 + \frac{\tau}{m_1} \vec{p}_1)}
\]

\[
= -i \int_0^{\tau'} \int_0 \int d^3 \vec{k} \Phi_{12}(k) \ e^{i k \left( \frac{\eta_1 - \eta_2}{m_1} \int \vec{E} - \vec{p}_2 - \frac{\tau}{m_2} \vec{p}_2 \right)}
\]

\[
\left( \frac{\partial}{\partial \vec{p}_2} - \frac{\tau}{m_2} \frac{\partial}{\partial \vec{r}_2} \right) \int d^3 \vec{r}_1 d^3 p_1 \ e^{i k (\vec{r}_1 + \frac{\tau}{m_1} \vec{p}_1)} \tag{A.3}
\]

Mainly this operator acts as a Fourier transform.
Appendix B

RPA approximation

At first the calculation for the classical case is done. The extension to the quantum regime will be obvious. We need the expressions which build up when the operator \((A.3)\) acts \(n\) times on the product of distribution functions at \(t = 0\). Calculating the Fourier action of \((A.3)\) when again acting on itself we get 

\[
\vec{\eta}_{jk}(\tau) = (\vec{q}_j - \vec{q}_k) \int^{\tau} \int^{\tau} \hat{E}
\]

\[
- i \int d^3 r_2 d^3 p_2 e^{i\vec{k}(\vec{r}_2 + \frac{\tau'}{m_2} \vec{p}_2)} \int_0^{\tau'} \int \frac{d^3 k}{(2\pi)^3} \Phi_{12}(k) e^{i\vec{k}(\vec{p}_{12}(\tau) - \vec{r}_2 - \frac{\tau'}{m_2} \vec{p}_2)} \otimes \\
\vec{k} \left( \frac{\partial}{\partial \vec{p}_2} - \frac{\tau}{m_2} \frac{\partial}{\partial \vec{r}_2} \right) \int d^3 r_1 d^3 p_1 e^{i\vec{k}(\vec{r}_1 + \frac{\tau}{m_1} \vec{p}_1)}
\]

\[
= - i \int \int \frac{d^3 k}{(2\pi)^3} \Phi_{12}(k) e^{i\vec{k}\vec{\eta}_{12}(\tau)} \frac{i\vec{k}\vec{k}'}{m_2} \frac{\tau' - \tau}{m_2} \otimes \\
\int d^3 r_2 d^3 p_2 e^{i\vec{r}_2(\vec{k}'' - \vec{k}) + \frac{\tau}{m_2} \vec{p}_2(\vec{k}' - \vec{k})} \int d^3 r_1 d^3 p_1 e^{i\vec{r}_1(\vec{r}_2 + \frac{\tau}{m_1} \vec{p}_1)}
\]

So, the second order of the RPA approximation is:

\[
\int \int \int \int \int \int \int \int \int \\
\int \int \int \int \int \int \int \int \\
( - i ) \int \int \frac{d^3 k'}{(2\pi)^3} \Phi_{23}(k') e^{i\vec{k}'\vec{\eta}_{23}(\tau')} e^{-i\vec{k}'(\vec{r}_3 + \frac{\tau'}{m_3} \vec{p}_3)} \vec{k}' \left( \frac{\partial}{\partial \vec{p}_3} - \frac{\tau'}{m_3} \frac{\partial}{\partial \vec{r}_3} \right) \otimes \\
( - i ) \int \int \frac{d^3 k}{(2\pi)^3} \Phi_{12}(k) e^{i\vec{k}\vec{\eta}_{12}(\tau)} \frac{i\vec{k}\vec{k}'}{m_2} \frac{\tau' - \tau}{m_2} \otimes 
\]

38
\[ \int d^2 e^{i\mathbf{r}_2 (\mathbf{k} - \mathbf{k}) + i \frac{\mathbf{p}_2}{m_2} (\mathbf{k} - \mathbf{k})} \int d^1 e^{i\mathbf{k} (\mathbf{r}_1 + \frac{\mathbf{r}}{m_1} \mathbf{p}_1)} . \]

In order to understand the scheme which builds up, we have a look at the third order:

\[ \int \int d^3 \tau''_3 \int \int d^2 \tau'_{23} \int \int d^1 \tau_1 \]

Further on we assume that the plasma is homogenous at \( t = 0 \). So, the distribution functions do not depend on the position at the beginning and the Fourier integrals due to the \( r_1, r_2 \) give products of delta functions; and the \( k \)-integrations simplify to:

\[ \int \int d^3 \tau''_3 \int \int d^2 \tau'_{23} \int \int d^1 \tau_1 \]

For higher orders we will get more and more terms than the two middle ones in the above equation. The particle-species being different depend on the electric field of the laser.
by the $\bar{\eta}_{ij}$ terms. For the same particle species these terms vanish. Due to the large ion mass we neglect all contributions of the ions but the first one. That means, particle one is considered to be an ion and the rest to be electrons, $\bar{\eta}_{12} = -\bar{\eta}_{e1}$ and $\Phi_{12}(k) = \Phi_{e1}(k)$. The time integrals are of convolution type. By using the Laplace transform the terms could be factorized. For the $n$th order operator acting on the product of $n$ homogenous distribution functions $f_e$ and on one inhomogeneous function $f_i$ we get

$$\left[ -\bar{\eta}_{ij} \right] = \left( -i \right) \int_0^t \int \frac{d^3k}{(2\pi)^3} \Phi_{ei}(k) e^{-i\vec{k} \cdot \vec{r}_e + \frac{\vec{p}_e}{m_e} \vec{r}_e} \vec{k} \frac{\partial f_0^e(\vec{p}_e)}{\partial \vec{p}_e}$$

$$\times \int_{c-i\infty}^{c+i\infty} \frac{ds}{2\pi i} e^{s\tau} (\Pi(\vec{k}, s) \Phi_{ee}(k))^{-1}$$

$$\times \int_0^\infty d\tau' e^{-s\tau'} e^{-i\vec{k} \cdot \vec{r}_e(\tau')} \int d^3p_i d^3r_i e^{i\vec{k} \cdot \vec{r}_i + \frac{\vec{p}_i}{m_e} \vec{r}_i} f_0^e(\vec{r}_i, \vec{p}_i)$$

with the RPA polarization function

$$\Pi(\vec{k}, s) = -i \int_0^\infty d\tau e^{-s\tau} i k^2 \frac{\tau}{m_e} \int d^3p_e e^{i\vec{k} \cdot \vec{r}_e} f_0^e(\vec{p}_e) .$$

Summing up all orders starting at $n = 1$ the terms $(\Pi\Phi)^{-1}$ result in a geometric sum. Adding the free propagator Eq. (2.11) we get the one particle electron distribution function in RPA approximation:

$$f_e(\vec{r}_e, \vec{p}_e, t) = \int_0^t f_e^0(\vec{p}_e) - \int_0^t \frac{d^3k}{(2\pi)^3} \Phi_{ei}(k) e^{-i\vec{k} \cdot \vec{r}_e + \frac{\vec{p}_e}{m_e} \vec{r}_e} \vec{k} \frac{\partial f_0^e(\vec{p}_e)}{\partial \vec{p}_e}$$

$$\times \int_{c-i\infty}^{c+i\infty} \frac{ds}{2\pi} e^{s\tau} \frac{1}{1 - \Pi(\vec{k}, s) \Phi_{ee}(k)}$$

$$\times \int_0^\infty d\tau' e^{-s\tau'} e^{-i\vec{k} \cdot \vec{r}_e(\tau')} \int d^3p_i d^3r_i e^{i\vec{k} \cdot \vec{r}_i + \frac{\vec{p}_i}{m_e} \vec{r}_i} f_0^e(\vec{r}_i, \vec{p}_i) .$$

The calculations done before are very similar in the quantum case, as all actions done on the classical derivative $\vec{k} \left( \frac{\partial}{\partial p} - \frac{\tau}{m} \frac{\partial}{\partial \tau} \right)$ also perform on the quantum one - sinh $\left[ \frac{\hbar}{2} \left( \frac{\partial}{\partial p} - \frac{\tau}{m} \frac{\partial}{\partial \tau} \right) \right]$:}

$$f_{e}^{\text{qu}}(\vec{r}_e, \vec{p}_e, t) = \int_0^t f_{e}^{0}(\vec{p}_e) - \int_0^t \frac{2}{\hbar} \int_0^t \frac{d^3k}{(2\pi)^3} \Phi_{ei}(k) e^{-i\vec{k} \cdot \vec{r}_e + \frac{\vec{p}_e}{m_e} \vec{r}_e} \sinh \left[ \frac{\hbar}{2} \frac{\vec{k}}{m_e} \left( \frac{\tau}{m_e} \frac{\partial}{\partial \vec{p}_e} \right) \right] \frac{\partial f_{e}^{0}(\vec{p}_e)}{\partial \vec{p}_e}$$

$$\times \int_{c-i\infty}^{c+i\infty} \frac{ds}{2\pi} e^{s\tau} \frac{1}{1 - \Pi^{\text{qu}}(\vec{k}, s) \Phi_{ee}(k)}$$

$$\times \int_0^\infty d\tau' e^{-s\tau'} e^{-i\vec{k} \cdot \vec{r}_e(\tau')} \int d^3p_i d^3r_i e^{i\vec{k} \cdot \vec{r}_i + \frac{\vec{p}_i}{m_e} \vec{r}_i} f_{e}^{0}(\vec{r}_i, \vec{p}_i) ,$$

where

$$\Pi^{\text{qu}}(\vec{k}, s) = -\frac{2i}{\hbar} \int_0^\infty d\tau e^{-s\tau} \sinh \left( \frac{\hbar k^2 \tau}{m_e} \right) \int d^3p_e e^{\frac{i\vec{k} \cdot \vec{r}_e}{m_e}} f_{e}^{0}(\vec{p}_e) .$$
denotes the quantum kinetic polarization function.

We can immediately extract the effective potential acting on the electrons:

$$

\Phi_{\text{eff}}(\vec{r}_e, t) = \int_{c-i\infty}^{c+i\infty} \frac{ds}{2\pi} e^{st} \int \frac{d^3k}{(2\pi)^3} e^{i\vec{k}\vec{r}_e} \frac{\Phi_{ei}(k)}{1 - \Pi(k, s) \Phi_{ee}(k)} \times \int_0^\infty \frac{d\tau'}{\epsilon^{+\tau'}} e^{-i\vec{k}\vec{\eta}_\tau(\tau')} \int d^3p d^3r e^{i\vec{k}\vec{r}_e} \frac{\Phi_{\text{eff}}(\vec{r}_e, \vec{p}_e)}{\epsilon - \frac{\vec{r}_e^2}{2\epsilon_{\text{eff}, e}^2}}. \tag{B.3}

$$

Further on, the equilibrium distribution functions are assumed to be Maxwellian,

$$
f_{e}^0 = \frac{n_{\text{e}, d}}{(2\pi m_{\text{e}, d}^2 \epsilon_{\text{e}, d}^3)^{3/2}} e^{-\frac{\vec{r}_e^2}{2m_{\text{e}, d}^2 \epsilon_{\text{e}, d}}} \tag{B.4}

$$

Additionally, we take a delta function for the space dependence of the initial ion distribution function, $\delta(\vec{r}_i - \vec{r}_0)$. With the thermal electron/ion velocity $v_{e,i}$ and the De Broglie wave number $k_B = \left(\frac{\hbar}{2m_{\text{e}, i}}\right)^{-1}$ the classical and quantum kinetic expressions for the polarization II, the dielectric function $\epsilon$ as well as the electron distribution function result in

$$
f_{\epsilon}^i(\vec{r}_i, \vec{p}_i, t) = \gamma I f_{\epsilon}^0(p_e) - \gamma I f_{\epsilon}^0(p_e) \int_0^t \int \frac{d^3k}{(2\pi)^3} \Phi_{\text{eff}}(\vec{k}, \tau) \times e^{-i\vec{k}(\vec{r}_e + \frac{\vec{q}_i}{m_{\text{e}, i}} \vec{p}_e)} e^{-\frac{\vec{p}_e^2}{2m_{\text{e}, i}^2 \epsilon_{\text{e}, i}}} \tag{B.5}

$$

$$

\epsilon(k, s) = 1 - \Pi(k, s) \Phi_{ee}(k) \tag{B.6}

$$

$$

\Pi(k, s) = \frac{n_{\text{e}, s}}{m_{\text{e}, s} v_{\text{e}, i}^2} \left(1 - \frac{s}{2 m_{\text{e}, i} v_{\text{e}, i}} e^{\frac{s}{2 m_{\text{e}, i} v_{\text{e}, i}}} \right) \tag{B.7}

$$

$$

\Pi^{ii}(k, s) = \frac{i}{\hbar k v_{\text{e}, i}^2} \left[ \frac{1}{e^{\frac{1}{2}(k v_{\text{e}, i} + i k)^2} - 1} + \frac{1}{e^{\frac{1}{2}(k v_{\text{e}, i} - i k)^2} - 1} \right] \tag{B.8}

$$

$$

\Phi_{\text{eff}}(\vec{k}, \tau) = \int_{c-i\infty}^{c+i\infty} \frac{ds}{2\pi} e^{st} e^{i\vec{k}\vec{r}_0} \frac{\Phi_{ei}(k)}{\epsilon(k, s)} \int_0^\infty d\tau e^{-s\tau} e^{-i\vec{k}\vec{\eta}_\tau(\tau')} \int d\tau' e^{-s\tau'} e^{-(k v_{\text{e}, i})^2} \tag{B.9}

$$

$$

\vec{\eta}_\tau(\tau') = \left( \frac{e}{m_{\text{e}, d}} - \frac{ze_i}{m_{\text{e}, i}} \right) \int_0^\tau \int \frac{d\tau'}{\epsilon^{+\tau'}} \vec{E}(\tau') \tag{B.10}

$$
Appendix C

Wigner Representation of the Kinetic Hierarchy

The content of this chapter is mostly taken unchanged from the book of Michael Bonitz [23] and should help the reader who is not quite familiar with the Wigner representation of the BBGKY-hierarchy. The only change was the substitution of $p$ by $\eta$ to remain consistent to the notation of the current work.

We consider the BBGKY-hierarchy in coordinate representation, which involves matrices of the type $F_{1...s}(r'_1, \ldots, r'_s; r''_1, \ldots, r''_s, t)$:

$$\left\{ i\hbar \frac{\partial}{\partial t} - H_{1...k}(r_1, \ldots, r_k) + H_{1...k}(r'_1, \ldots, r'_k) \right\} F_{1...k}(r_1, \ldots, r_k; r'_1, \ldots, r'_k, t)$$

$$= \eta \sum_{i=1}^{k} \sum_{s_{k+1}} \int d r_{k+1} \{ V(r_i - r_{k+1}) - V(r'_i - r_{k+1}) \}$$

$$\times F_{k+1}(r_1, \ldots, r_{k+1}; r'_1, \ldots, r'_k, r_{k+1}, t) \quad .$$

Introducing center of mass and relative coordinates, $R_i$ and $r_i$ for each particle, according to $r'_i = R_i + r_i/2$ and $r''_i = R_i - r_i/2$, or, vice versa, $R_i = (r'_i + r''_i)/2$ and $r_i = r'_i - r''_i$, the above matrix transforms into

$$F_{1...s}(r'_1, \ldots, r'_s; r''_1, \ldots, r''_s, t) = F_{1...s}(R_1 + r'_1/2, \ldots, R_s + r'_s/2; R_1 - r'_1/2, \ldots, R_s - r'_s/2, t)$$

$$= \tilde{F}_{1...s}(R_1, r_1, \ldots R_s, r_s, t) = \frac{1}{n^s} \tilde{f}_{1...s}(R_1, r_1, \ldots R_s, r_s, t) \quad .$$

We can rewrite the hierarchy equations suppressing the spin variables:

$$\left\{ i\hbar \frac{\partial}{\partial t} - H_{1...k}(R_1 + r_1/2, \ldots, R_k + r_k/2) + H_{1...k}(R_1 - r_1/2, \ldots, R_k - r_k/2) \right\} \tilde{f}_{1...k}(R_1, r_1, \ldots R_k, r_k, t)$$

$$= \sum_{i=1}^{k} \int d R_{k+1} \{ V(R_i - R_{k+1} + r_i/2) - V(R_i - R_{k+1} - r_i/2) \} \tilde{f}_{k+1}(R_1, r_1, \ldots R_k, 0, t) \quad . \quad (C.1)$$

42
The kinetic energy terms and the binary interaction potentials \( V_{ij} \) in the Hamiltonians transform to \((r_{ij} = r_i - r_j; R_{ij} = R_i - R_j)\)

\[
V'(r_i' - r_j') - V(r_i'' - r_j'') = V(R_{ij} + \frac{r_{ij}}{2}) - V(R_{ij} - \frac{r_{ij}}{2})
- \frac{\hbar^2}{2m_i} (\nabla_{r_i'}^2 - \nabla_{r_j''}^2) = -2 \frac{\hbar^2}{2m_i} \nabla R_i \nabla r_i.
\]

We now introduce the Wigner transformation with respect to the relative coordinates \(r_1, \ldots, r_s\) and the inverse transform according to

\[
\tilde{f}_{1\ldots s}(R_1, r_1, \ldots, R_s, r_s, t) = \int \frac{dr_1}{(2\pi \hbar)^3} \cdots \frac{dr_s}{(2\pi \hbar)^3} \exp \{-i \frac{r_1 r_1 + \cdots + r_s r_s}{\hbar}\} \times f_{1\ldots s}(R_1, r_1, \ldots, R_s, r_s, t)
\]

(C.2)

\[
\tilde{f}_{1\ldots s}(R_1, r_1, \ldots, R_s, r_s, t) = \int dp_1 \cdots dp_s \exp \{i \frac{r_1 r_1 + \cdots + r_s r_s}{\hbar}\} \times f_{1\ldots s}(R_1, p_1, \ldots, R_s, p_s, t).
\]

(C.3)

The Wigner transform (C.2) of Eq. (C.1) is

\[
\left\{ i \hbar \frac{\partial}{\partial t} + i \hbar \sum_{i=1}^{k} \frac{p_i}{m_i} \nabla R_i \right\} f(R_1, p_1, \ldots, R_k, p_k, t) - \sum_{1 \leq i < j \leq k} V_k^{(ij)} - \sum_{i=1}^{k} \sum_{i=1}^{k} U_k^{(i)} = \sum_{i=1}^{k} F_{k+1}^{(i)}.
\]

where only the non-trivial terms are those containing the external potential or the interaction potential which are denoted \( U_k^{(i)}, V_k^{(ij)} \) and \( F_{k+1}^{(i)} \), respectively. We consider \( V_k^{(ij)} \) more in detail,

\[
V_k^{(ij)} = \int \frac{dr_1}{(2\pi \hbar)^3} \cdots \frac{dr_k}{(2\pi \hbar)^3} \exp \{-i \frac{r_1 r_1 + \cdots + r_k r_k}{\hbar}\} \times \left\{ V(R_{ij} + \frac{r_{ij}}{2}) - V(R_{ij} - \frac{r_{ij}}{2}) \right\} \tilde{f}_{1\ldots k}(R_1, r_1, \ldots, R_k, r_k, t)
\]

which, after using for \( \tilde{f} \) Eq. (C.3), transforms to

\[
\int \frac{dr_1}{(2\pi \hbar)^3} \cdots \frac{dr_k}{(2\pi \hbar)^3} \exp \{-i \frac{r_1 r_1 + \cdots + r_k r_k - \eta_1 r_1 - \cdots - \eta_k r_k}{\hbar}\} \times \left\{ V(R_{ij} + \frac{r_{ij}}{2}) - V(R_{ij} - \frac{r_{ij}}{2}) \right\} \tilde{f}_{1\ldots k}(R_1, \eta_1, \ldots, R_k, \eta_k, t).
\]

The integrals over all coordinates and momenta, except those with the indices \( i \) and \( j \) can be carried out according to
\[ \int \frac{dr_a}{(2\pi \hbar)^3} d\eta_a \exp \{-i(p_a - \eta_a) r_a / \hbar\} G(\eta_a) = G(p_a), \]

whereas the argument of the remaining exponential is conveniently rearranged as \( p_i r_i + p_j r_j - \eta_i r_i - \eta_j r_j = (p_i - \eta_i)(r_i - r_j) + (p_i - \eta_i + p_j - \eta_j)r_j. \) The second term yields \( \delta(p_i - \eta_i + p_j - \eta_j), \) and we finally obtain

\[
V^{(ij)}_k = \int \frac{dr_{ij}}{(2\pi \hbar)^3} d\eta_i \exp \{-i(p_i - \eta_i) r_{ij} / \hbar\} \times \left\{ V(R_{ij} + \frac{r_{ij}}{2}) - V(R_{ij} - \frac{r_{ij}}{2}) \right\} \times f_{1...k}(R_1, p_1, \ldots, R_i - 1, p_i - 1, R_i, \eta_i, R_{i+1}, p_{i+1}, \ldots, R_k, p_k, t). \]

In a similar way, we transform \( U^{(i)}_k \) and \( F^{(i)}_{k+1}, \) with the final result

\[
U^{(i)}_k = \int \frac{dr_i}{(2\pi \hbar)^3} d\eta_i \exp \{-i(p_i - \eta_i) r_i / \hbar\} \times \left\{ U(R_i + \frac{r_i}{2}) - U(R_i - \frac{r_i}{2}) \right\} \times f_{1...k}(R_1, p_1, \ldots, R_{i-1}, p_{i-1}, R_i, \eta_i, R_{i+1}, p_{i+1}, \ldots, R_k, p_k, t), \]

\[
F^{(i)}_{k+1} = \int \frac{dr_i}{(2\pi \hbar)^3} d\eta_i dR_{k+1} dp_{k+1} \exp \{-i(p_i - \eta_i) r_i / \hbar\} \times \left\{ V(R_{i,k+1} + \frac{r_i}{2}) - V(R_{i,k+1} - \frac{r_i}{2}) \right\} \times f_{1...k+1}(R_1, p_1, \ldots, R_i, \eta_i, \ldots, R_k, p_k, R_{k+1}, p_{k+1}, t). \]
