Abbreviation

Abbreviation	Full name
(i)OSN	(immature) olfactory sensory neuron
(M)OB	(main) olfactory bulb
(T-)PBS	(Triton-) Phosphate buffered saline
AC3	Adenylyl cyclase 3
AOB	Accessory olfactory bulb
ATP	Adenosine triphosphate
Big2	Brain-derived, immunoglobulin superfamily molecule-2
bp	Base pairs
BSA	Bovine serum albumin
caGs	Constitutively active G _{αs} subunit
cAMP	Cyclic adenosine monophosphate
CIP	Calf intestine phosphatase
CNGC	Cyclic nucleotide gated channel
CV	Coefficient of variation
DNA	Deoxyribonucleic acid
E(number)	Embryonic age ()
EPL	External plexiform layer
ES	Embryonic stem cell
EtBr	Ethidium bromide
GAP43	Growth associated protein 43
GFP	Green fluorescent protein
GG	Grüneberg ganglion
Glom	Glomerular layer
GPCR	G protein coupled receptors
GrL	Granule layer
GTP	Guanine triphosphate
iOSN	Immature OSN
IPL	Internal plexiform layer
IRES	Internal ribosomal entry site
lacZ	β-galactosidase
LB	Lysogeny broth
LB-Crab	LB with carbenicilin
MOE	Main olfactory epithelium
MT	Mitral layer
NaCl	Sodium Chloride
NCAM	Neural cell adhesion molecule
Nrp	Neuropilin
O.C.T.	Optimum cutting temperature (freezing medium)
OCNC1	Cyclic nucleotide gated channel alpha 2
OMP	Olfactory marker protein
ONL	Olfactory nerve layer
OR	Odorant receptor
PCR	Polymerase chain reaction
PD(number)	Post natal day ()
PFA	Paraformaldehyde
RFP	Red fluorescent protein
RNA	Ribonucleic acid

Abbreviation	Full name
Robo	Round about
Sema	Semaphorin
SO	Septal organ
TAAR	Trace amine-associated receptor
TGV	Total glomerular volume
V1R	VR class 1
V2R	VR class 2
VNO	Vomer nasal organ
VR	Vomer nasal receptor
YFP	Yellow fluorescent protein
z-stack	Optical sections in the z direction
β 2AR	β 2-adrenergic receptor

1 Summary

Odorant receptor (OR) genes were discovered by Buck and Axel (1991). Around 1,100 ORs are expressed in mouse olfactory sensory neurons (OSNs) in a monoallelic and monogenic manner (Chess et al., 1994). These OSNs are located in the main olfactory epithelium and project their axons to the olfactory bulb (OB) where they form homogeneous glomeruli. The glomeruli are formed at conserved positions in the OB. Several laboratories have studied the mechanisms that guide the OSN axons to their target where they form synapses with the mitral cells that convey the olfactory signal to other brain regions. Several theories have emerged to explain these mechanisms, but none has yet achieved full explanation for the precise axonal wiring in the mouse olfactory system.

This thesis describes three approaches for gaining further insight into the mechanisms that govern axonal wiring. In the first approach a gene-targeting vector was designed to target the M71 locus and knock in the constitutively active G_{os} subunit (caGs) in M71-expressing OSNs. It has been reported that OSNs expressing caGs shift their glomerular position to a posterior position in the OB. However this shift was shown only with transgenic mice. A gene-targeted expression from the M71 locus would have provided a better understanding, because it is closer to the native mechanism. Unfortunately the assembly of the targeting vector was more difficult than anticipated and the project was suspended after a year.

The second approach was an empirical study of the fundamental components of the olfactory system. Green-fluorescent OSNs in 11 gene-targeted strains coexpressing GFP with a specific OR gene were evaluated quantitatively. It was shown that their OSN number is proportional to the respective total glomerular volume (TGV). These data enable new methods of quantifying and qualifying the properties of the OSN population and allow an estimate of the OSN numbers from the easier to measure TGV, which is much easier to measure than counting cells. With the first broad collection of

complete datasets of the number of OSNs, several other results could be extrapolated. The full datasets allowed an in-depth analysis of the sampling error for the 11 strains and established a well-grounded threshold for sampling of the main olfactory epithelium from every fifth section. I also demonstrated that these 11 strains have different stabilities of expression in terms of numbers of labeled OSNs, measured by the coefficient of variation (CV), with the strain MOR23-IRES-tauGFP being the most stable. It was also shown that most of the strains tested have a unique expression pattern along the anterior-posterior axis, except for OR-expressing OSNs in the classical zone 1, which displayed a similar expression pattern. For this study several reporter genes were expressed from the M71 locus, in addition gene replacements and downregulation of M71 were measured as well. These strains showed differences in the OSN numbers compared to M71-IRS-*tau*lacZ expressing OSNs. The latter being expressed three times more than in the strains expressing fluorescent marker proteins. However each strain maintained the characteristic expression pattern for M71.

The final approach discussed in this thesis is the influence of a conditional Neuropilin-1 (Nrp1) knockout on axonal wiring of the mouse olfactory system. It has been reported that the position of a glomerulus in the OB along the anterior-posterior axis is determined by a gradient of Nrp1. However this finding was in mice expressing a transgene. Here an approach was chosen to generate a better test of this hypothesis. Conditional knockouts of Nrp1 in M71-expressing OSNs were generated, exploiting the unusual feature of monoallelic expression of ORs to provide a control in the same individual mouse. The results show not a gradual shift of glomeruli to the anterior OB as reported previously (Imai et al., 2009), but the formation of ectopic glomeruli in the anterior bulb, resembling the effect an adenylyl cyclase 3 (AC3) knockout has on M71-expressing OSNs. This phenotype is established directly at the onset of glomerular formation and is maintained during adulthood. These finding leads to the conclusion that the signal transduction cascade of OSNs is indeed linked to the expression of Nrp1, but a simple Nrp1-gradient hypothesis cannot explain the phenotype M71-expressing OSNs.

2 Introduction

Of the five senses the sense of smell is probably the most complex one to investigate. While for example the sense of taste has five different receptor types to coordinate, the sense of smell has to coordinate hundreds of different olfactory sensory neurons (OSNs) each expressing a single odorant receptor (OR) gene (Chess et al., 1994). The discovery of the OR genes 24 years ago has triggered a substantial amount of research on the mechanism that determines and regulates axonal wiring in the mouse olfactory system.

2.1 Anatomy of the mouse olfactory system

The olfactory system of mice consists of several organs, which express many types of molecular chemosensory receptors (Figure 2.1). The first of these organs is the Grüneberg ganglion (GG), located at the tip of the nose of the mouse. The chemosensory neurons there probably express receptors for early warning signals (Brechtbühl et al., 2008). The vomeronasal organ (VNO) is situated on the septum in the nasal cavity and receives mostly information from pheromones and kairomones (Døving and Trotier, 1998). The most prominent chemosensory receptors in the VNO are the vomeronasal receptors (VR) and will be further described in Chapter 2.4. Another sensory organ is also situated on the septum, the septal organ (SO). In the SO a subset of olfactory sensory neurons (OSNs) can be found (Ma et al., 2003b, Tian and Ma, 2004). Most OSNs reside within the main olfactory epithelium (MOE). OSNs in SO and MOE send their axons through the cribriform plate to the main olfactory bulb (MOB), where they form glomeruli that are homogeneous for a single OSNs type.

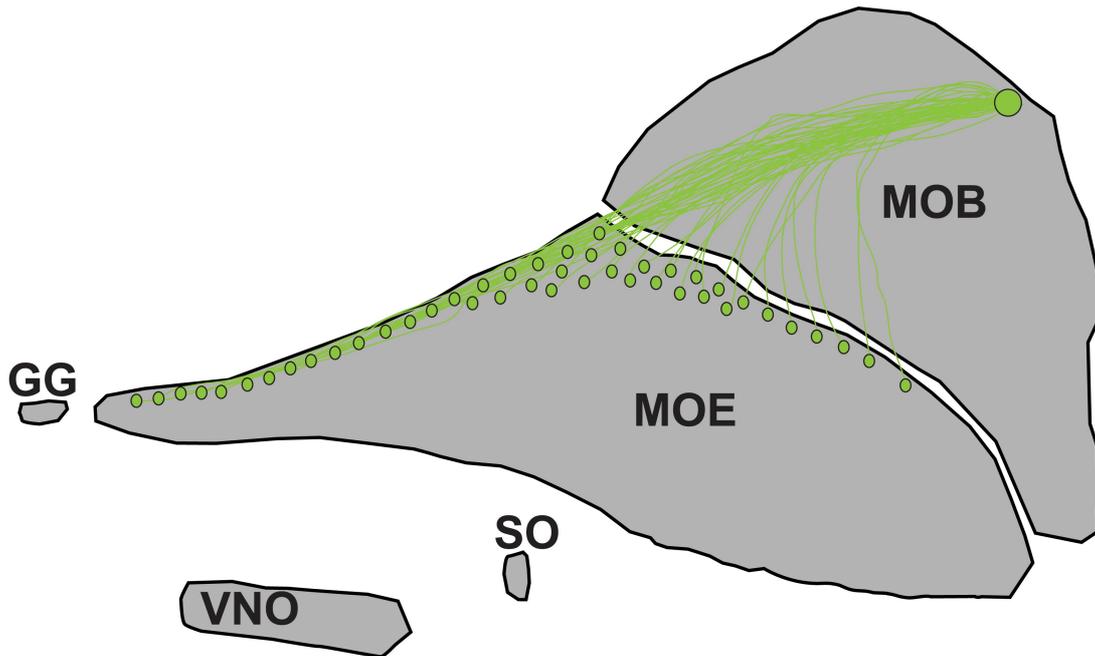

Figure 2.1 Mouse olfactory system

Representative sagittal map of the mouse olfactory system showing the different sensory organs: Grüneberg ganglion (GG), vomeronasal organ (VNO), septal organ (SO) and main olfactory epithelium (MOE). OSNs (small green dots) located in MOE project their axons to the mouse olfactory bulb (MOB) to form homogeneous glomeruli (large green circle).

2.2 Olfactory receptors (ORs) and olfactory sensory neurons (OSNs)

The OR gene family is the largest gene family in the mammalian genome. It was discovered by Linda Buck and Richard Axel in 1991 (Buck and Axel, 1991) and recognized with the 2004 Nobel Prize in Physiology or Medicine. The OR genes are expressed in OSNs monogenically and monoallelically (Chess et al., 1994), which makes them an interesting model for the study of gene choice. Recent studies estimate that approximately 10 million mature OSNs are present in an eight-week old mouse (Kawagishi et al., 2014).

Most OSN cell bodies reside within the middle layer of the main olfactory epithelium (Strotmann et al., 1996). The MOE is layered from basal to apical along the maturation of OSNs (Nickell et al., 2012). The basal layer provides the progenitor OSNs, which develop to immature OSNs (iOSNs), determined by the expression of GAP43. Mature OSNs are detected by their expression

of the olfactory marker protein (OMP) and they are situated in the apical half of the epithelium (Figure 2.2).

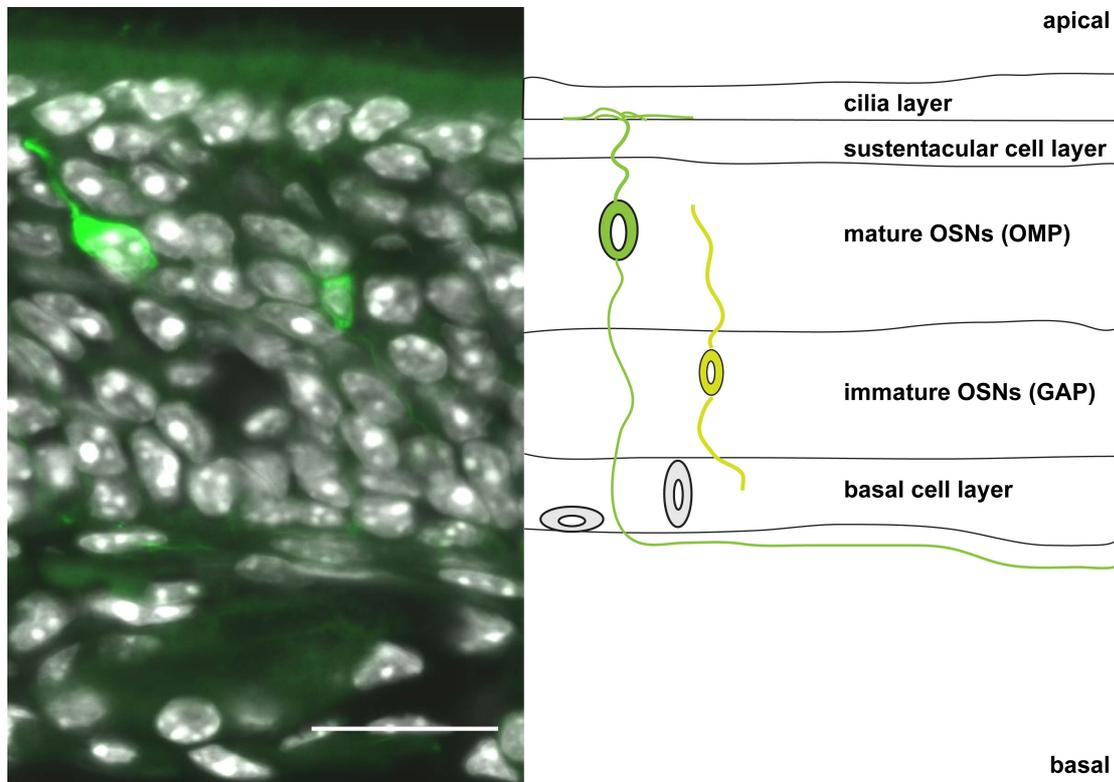

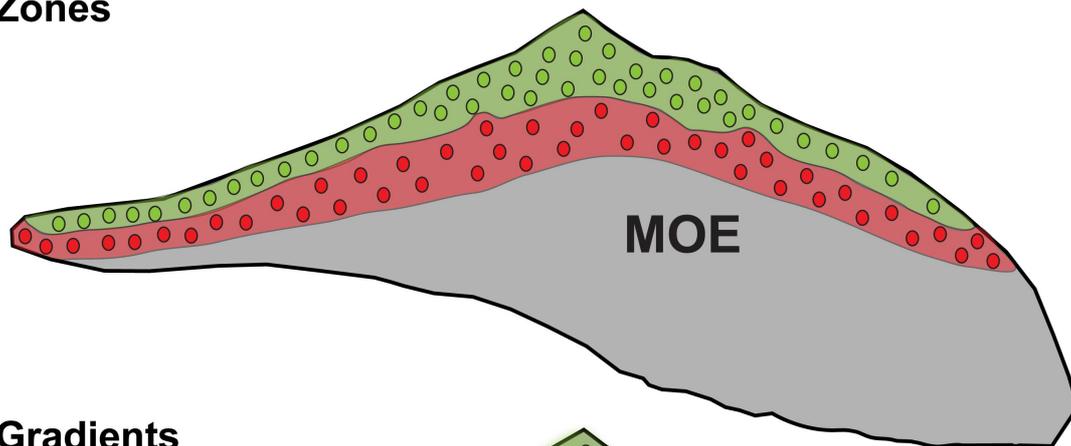

Figure 2.2 Olfactory epithelium layers

Schematic overview of the layers in the main olfactory epithelium from apical to basal along a coronal section of aPD21 M71-IRES-tauGFP mouse taken with a confocal microscope. OSN progenitor cells are formed from the basal cells (grey). While maturing the immature OSNs (light green) express GAP and move in apical direction. Dendrite and axon begin to form. Cell bodies of mature OSNs (green) are in the apical half of the epithelium. They have fully formed dendrites crossing the sustentacular cell layer and cilia spreading on the apical side. Mature OSN axons project to the olfactory bulb. The mature OSN layer is characterized by OMP expression. Scale bar: 20 μ m

It has been established that OSNs expressing a specific OR are not spread homogeneously across the whole surface of the MOE. The first studies identify four discrete zones of expression, arranged roughly from dorsal to ventral MOE (Ressler et al., 1993). Later studies gave rise to the idea that each OR-expressing OSN population is expressed in a unique gradient across the epithelium (Miyamichi et al., 2005). Recent unpublished studies in our lab suggest an intermediate scenario. The OR gene family can be divided into two classes. Class I ORs are expressed exclusively in the dorsal area and project to anterior-dorsal region of the bulb (Tsuboi et al., 2006), while class II ORs are expressed in all zones of the MOE (Figure 2.3).

Zones

Gradients

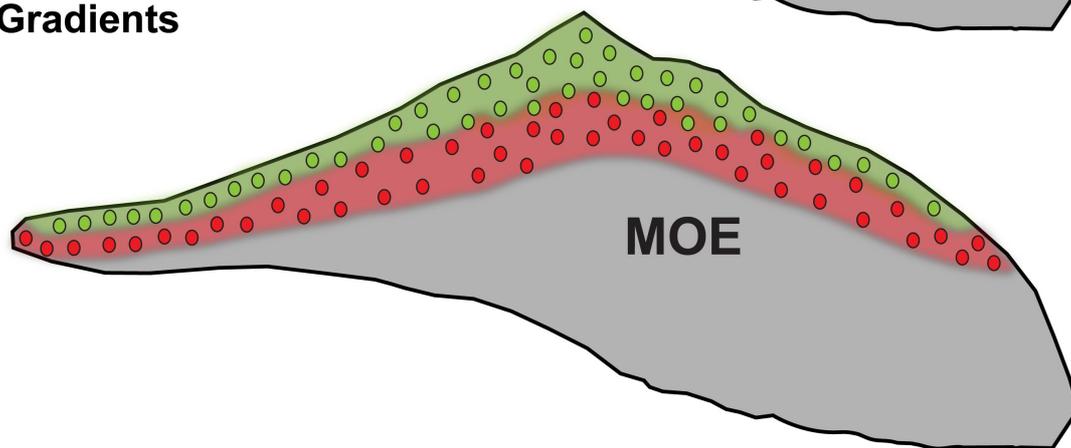

Figure 2.3 Illustration of zones and gradients

This sketch illustrates the difference between the theory of OSN expression in zones and in gradients. For zonal expression each OSN population (green & red) is confined to a specific zone (historical four with the green are representing zone 1 and the red area zone 2). Each OSN population would fall in one of these zones. In the gradient theory each OSN population would be expressed preferentially also in its own zone, however, also in a stripe overlapping with the zones of one or more other OSN population.

Since 1991, approximately 1,100 OR genes have been identified in mouse (Zhang and Firestein, 2002), located on most chromosomes. The structure of these ORs contains seven-transmembrane spanning regions, similar to other G-protein coupled receptors such as the $\beta 2$ adrenergic receptor, but there is a substantial variance in sequence (Liu et al., 2003). ORs are expressed already very early in development and can be detected by antibody staining as early as embryonic age 12 (E12) in cilia of OSNs (Schwarzenbacher et al., 2005). These receptors are not only expressed in the cilia of the OSNs but can also be detected in their axon terminal (Barnea et al., 2004, Strotmann, 2004). Ca^{2+} influx and cyclic adenosine monophosphate (cAMP) as second messenger in the signaling cascade (Maritan et al., 2009) were also observed in early OSNs.

The zonal expression of a population of OSNs as well as the regulation of monogenic expression of the ORs in OSNs is still not fully understood. Several groups have been working on the issue of gene choice and the regulation of OR expression and suppression. Once an OR is chosen and successfully expressed, the OSN never changes this chosen OR. However there are no genetic alterations of the OR locus accompanying gene choice (Li et al., 2004). Expression of a functional receptor is important for a stable expression of this OR through the OSNs life. If the OR is not functional another OR gene is chosen for expression (Shykind et al., 2004). However the alternate choice does not have to originate from the same gene clusters, as shown with the highly related mOR37 gene cluster (Bader et al., 2010). The OR sequence is sufficient for silencing expression other OR genes (Nguyen et al., 2007) even from transgenic ORs. The sequence of untranslatable OR mRNA is sufficient for an effective silencing of other ORs (Lewcock and Reed, 2004). There is a hierarchy in the choice of an OR (Hirota et al., 2007) where the class is determined before the specific OR.

Recently several factors regulating the gene choice haven been discovered. The regulatory element called the P element was reported in 2011 in this lab (Khan et al., 2011). The structure of OR promoters has been revealed a year later (Plessy et al., 2012). The first initiator for OR expression has been discovered, with downregulation of LSD1 associated with stabilization of OR gene choice (Lyons et al., 2013).

2.3 Oddities of OSN populations

Of the ~1,100 ORs in mouse only a few percent have been characterized in some detail. But already several OSN populations are reported to have remarkable and so far unique expression patterns. For example OSNs expressing the receptor SR1, which represent one of the largest OSN populations, constitute half of all OSNs situated in the septal organ (Tian and Ma, 2004, Figure 2.4). This broad expression is even more interesting since SR1 has a very broad response profile for an OR (Grosmaître et al., 2009).

Another interesting gene family is the mOR37 gene family, with an unusual expression pattern in a patch in the middle of the MOE on one turbinate. However a transgene expression of the mOR37C leads to expression of the OR outside of this patch (Strotmann et al., 2009, Bader et al., 2010).

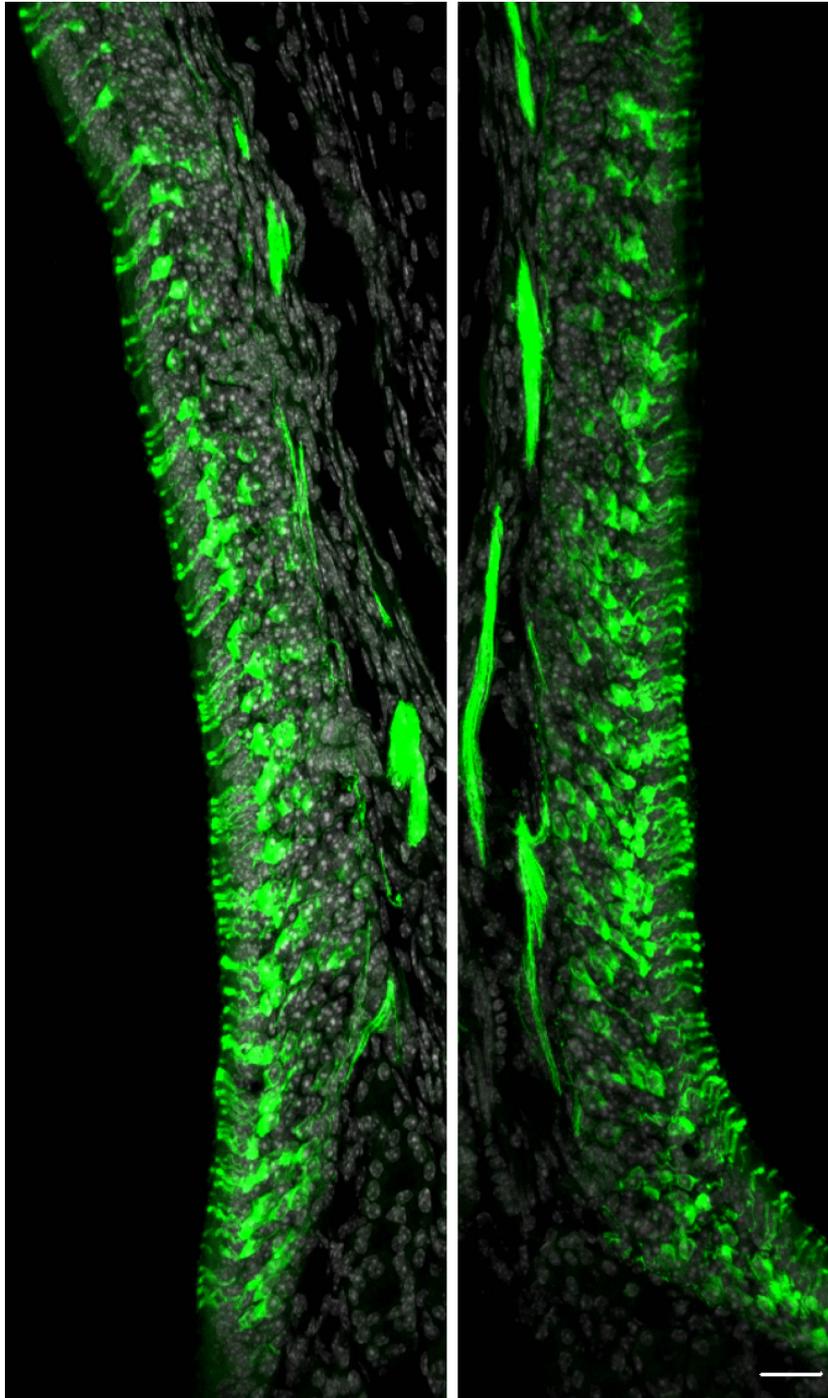

Figure 2.4 Example of SR1 expression in the septal organ

Confocal image of coronal 12 μm section of the septal organ of a PD21 SR1-IRES-tauGFP mouse. Both images are from the same coronal section; the septum was removed. Green intrinsic fluorescence shows OSNs expressing SR1. The strong green fluorescent lines close to the septum are the axon bundles heading towards to the olfactory bulb. DAPI staining in grey. Scale bar: 20 μm .

2.4 TAARs & VRs

Olfactory receptors are not the only chemosensory receptor families expressed in the olfactory system. Another family is the vomeronasal receptors (VRs), which are expressed in the vomeronasal organ (VNO) that is situated on the septum and senses pheromones. VR genes are the largest receptor gene family expressed in VNO, constituting almost all of the sensory neurons. VRs can be divided into two subfamilies (called V1R and V2R). V1Rs are expressed in the apical VNO epithelium while V2Rs are expressed in the basal VNO epithelium. Their axons project to the accessory olfactory bulb (AOB) situated dorsally and posterior of the MOB (Figure 2.5). The separation between V1R and V2R is still maintained in the AOB, the V1R glomeruli occupying the dorsal half of AOB while the V2R glomeruli occupy the ventral half of the AOB. But compared to the OSNs, only V1Rs are expressed similarly in a monogenic fashion, while V2Rs are not (Roppolo et al., 2007). It is also interesting to note that in mouse subspecies the VR repertoire differs in terms of the functional VR genes (Wynn et al., 2012).

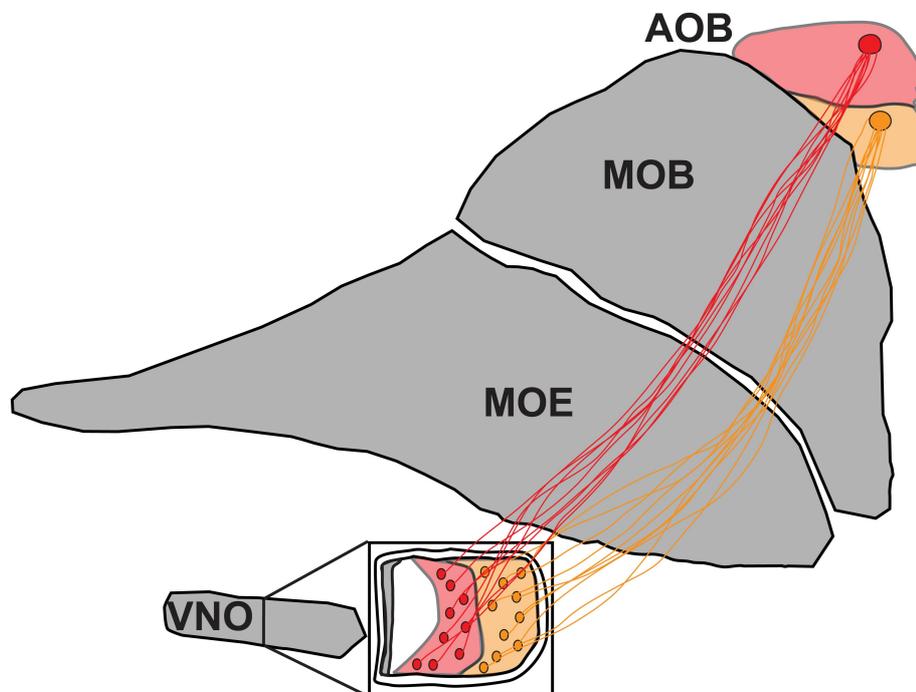

Figure 2.5 Axonal wiring of the vomeronasal system

Schematic overview of the axonal wiring of the VNO to the AOB in sagittal view. The VNO in coronal view (box) consists of cavernous tissue (grey), basal epithelium with V2Rs (orange) and apical epithelium with V1Rs (red). Both chemosensory neuron types send their axons to representative zones in the AOB. V1R to the dorsal half and V2R to the ventral half of the AOB.

Another recently discovered gene family is expressed in the MOE, the trace amine-associated receptors (TAARs). They are coexpressed with ORs but have the same signal transduction cascade, the G_{α} olfactory subunit ($G_{\alpha\text{olf}}$), as mature OSNs (Liberles and Buck, 2006). They are closely related to OR genes, explaining this similarity (Pacifico et al., 2012). It has been shown that TAAR-expressing sensory neurons respond to the odors of predators and other odors that trigger aversive reactions (Dewan et al., 2013). If a TAAR gene is deleted, TAAR expressing sensory neurons tend to express other TAARs rather than ORs. TAAR-expressing neurons project to a dorsal area in MOB, in between the areas D1 and D2. It seems that TAAR-expressing cells do not maintain such a strict homogeneity in their glomeruli as OSNs do (Pacifico et al., 2012).

2.5 Signaling

The primary task of a functional OR is the detection of odorants. Since ORs are G-protein coupled receptors (GPCRs) the molecular events following binding of an odorant by the OR are similar to other GPCRs and were established shortly after the discovery of the ORs themselves (Levy et al., 1991). The ORs are expressed early in development at E12. Other important factors such as NCAM and Big2 are expressed at E11 and E14, respectively (Saito et al., 1998).

If an odorant is bound to an OR, the the G_{α} subunit is activated by binding a GTP (guanosine tri-phosphate). In immature OSNs the activation is by the $G_{\alpha\text{S}}$ subunit, while after E14 (Saito et al., 1998) the $G_{\alpha\text{olf}}$ subunit is used for signal transduction (Figure 2.6).

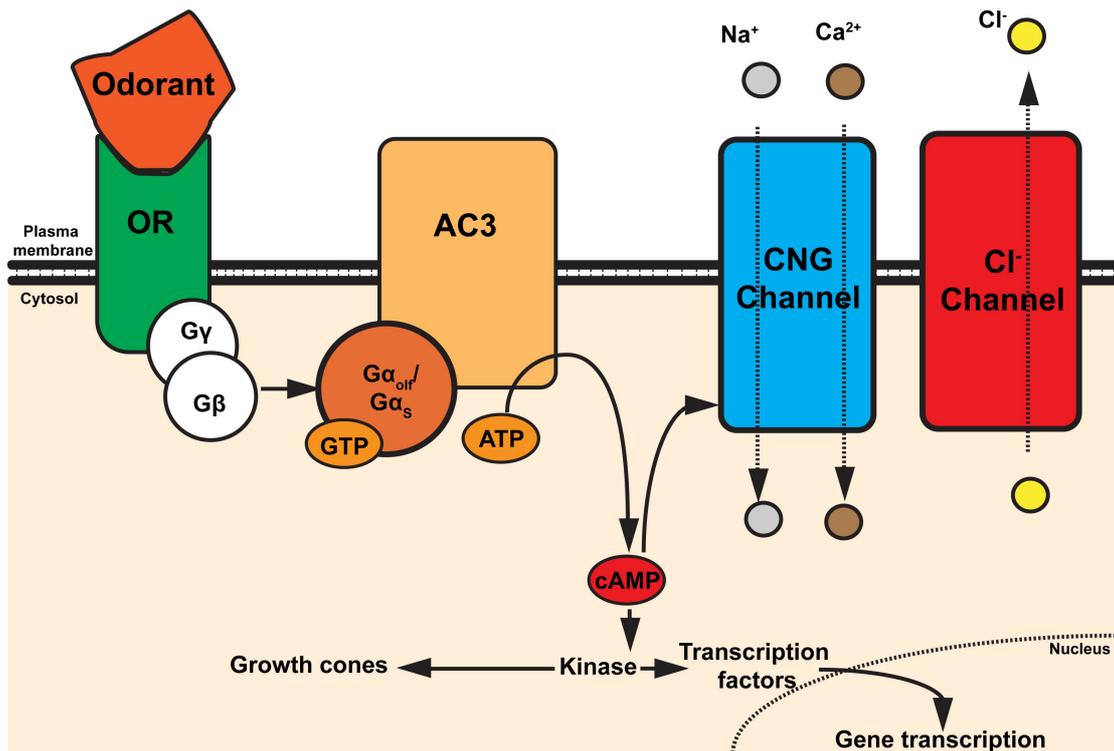

Figure 2.6 Signal transduction in OSNs

Schematic overview of the signaling transduction cascade in OSNs. Odorant is bound by OR. The G_{α} subunit (either G_{α_s} in immature or $G_{\alpha_{olf}}$ in mature OSNs) is activated and in turn activates AC3. AC3 will transform ATP into the second messenger cAMP, which will then activate kinase towards the growth cone and/or transcription factors. cAMP will also open CNG channels, where the Na^{+} and Ca^{2+} influx causes a depolarization of the cell membrane which will ultimately lead to an action potential.

The activated $G_{\alpha_{olf}}$ subunit is binding the adenylyl cyclase 3 (AC3), which transforms adenosine triphosphate (ATP) to cAMP. The second messenger cAMP is the critical signaling molecule in OSNs (Firestein et al., 1991). Mice with a knockout of the AC3 gene have viable OSNs but multiple ectopic glomeruli are formed and wiring defects are seen (Zou et al., 2007). AC3 and $G_{\alpha_{olf}}$ are also the first steps in the signal transduction cascade in the septal organ, supporting further the close relationship between the SO and MOE (Ma et al., 2003a). However, the same cascade does not apply to the VNO. For instance, $G_{\alpha_{olf}}$ could not be detected in the VNO, but low traces of AC3 were found (Berghard et al., 1996). Consequently, the VNO can still detect odors and pheromones even after a deletion of AC3 (Trinh and Storm, 2003).

The primary targets for the second messenger cAMP in the signaling cascade are the cyclic nucleotide gated (CNG) channels. When cAMP binds to the CNG channels, they open and allow the influx of sodium (Na^{+}) and

calcium (Ca^{2+}) ions. This influx of cations leads to a depolarization of the membrane and ultimately to the formation of action potentials. The depolarization is further supported by the opening of chloride ion (Cl^-) channels. The critical role of CNG channels is emphasized by a deletion of CNG channels in mice, resulting in profound anosmia (Brunet et al., 1996).

Three studies report other interesting observations concerning the modulation of the signal transduction cascade in OSNs. The first study shows that a complex of ORs with other GPCRs strengthens the localization of all GPCRs in the plasma membrane (Bush et al., 2007). The second study identifies PI3k as a mediator of inhibitory signaling in OSNs (Ukhanov et al., 2010). PI3k is enforcing G-protein signaling and thus PI3k expression leads to a faster rise time of the signaling cascade and stronger negative feedback to suppress expression of other ORs. The third study shows that OR expression increases AC3 expression, which then makes OR choice permanent (Dalton et al., 2013).

2.6 Development

Since the sense of smell is one of the most important senses for mice after birth and later in life, it is not surprising that ORs are expressed early in development and that OSNs mature quickly. The first expression of ORs (for example MOR256-17) can be detected by E12 in the dendritic knob (Schwarzenbacher et al., 2005). By E13 most ORs are expressed, but in unique, adult-like patterns and with a unique timing (Rodriguez-Gil et al., 2010). At the same time (E11-14) OSNs can also be detected in the cribriform mesenchyme, where they are thought to support the projecting axons from the epithelium to the olfactory bulb (Schwarzenbacher et al., 2004). About two days later in development, at E15.5, the first axons (shown for P2-IRES-*taulacZ*) can be detected in the OB (Royal and Key, 1999). OSNs are fully responsive by E16.5 (shown for S1 and MOR23) and glomeruli start forming directly after birth (Lam and Mombaerts, 2013). The OB interneurons move to the bulb at E14.5 and differentiate by PD21. Their identity is autonomously

defined in the lateral ganglionic eminence (LGE) and is irreversible (Tucker et al., 2006).

Even with the onset of OR expression in early development, the development still continues to mature age at 10-12 weeks (Pomeroy et al., 1990). The population of M72-expressing OSNs is maintained and stable and their glomerular number is consistent even after 24 months after birth (Richard et al., 2010).

The maturation is dependent on the activity of the OSNs, especially in glomerular formation. The M71 and M72 glomeruli were reported to become more homogeneous with development, from PD10 to PD60 (Zou et al., 2004). Glomerular development can be accelerated by odor training and exposure (Kerr and Belluscio, 2006).

OSNs maintain their plasticity even at old age (Jones et al., 2008). After naris closure, the OSN number and glomerular volume for P2-expressing OSNs do recover (Cummings and Belluscio, 2010).

2.7 Axonal wiring

One of the most impressive feats in the mouse olfactory system is the precise projection of OSN axons to the olfactory bulb to form glomeruli (Ressler et al., 1994). These glomeruli are formed homogeneously by axons of OSNs expressing the same OR (Treloar et al., 2002), illustrated as an example in [Figure 2.7](#)). All OSN populations project their axons to conserved positions in the olfactory bulb ([Figure 2.8](#)). Before reaching the position of their glomeruli the axons travel across the outer olfactory nerve layer until they are close to the glomerular position (Au et al., 2002), branching only within the glomerular position (Klenoff and Greer, 1998). Other axons expressing the same OR are needed for glomerular stability (Ebrahimi and Chess, 2000). Glomeruli start forming after birth and their number increases until more than 12 weeks after birth (LaMantia et al., 1992, Pomeroy et al., 1990). The general position of the glomeruli for a given OSN population is

consistent but the number of glomeruli varies in some populations, for example in P2-expressing OSNs (Schaefer et al., 2001).

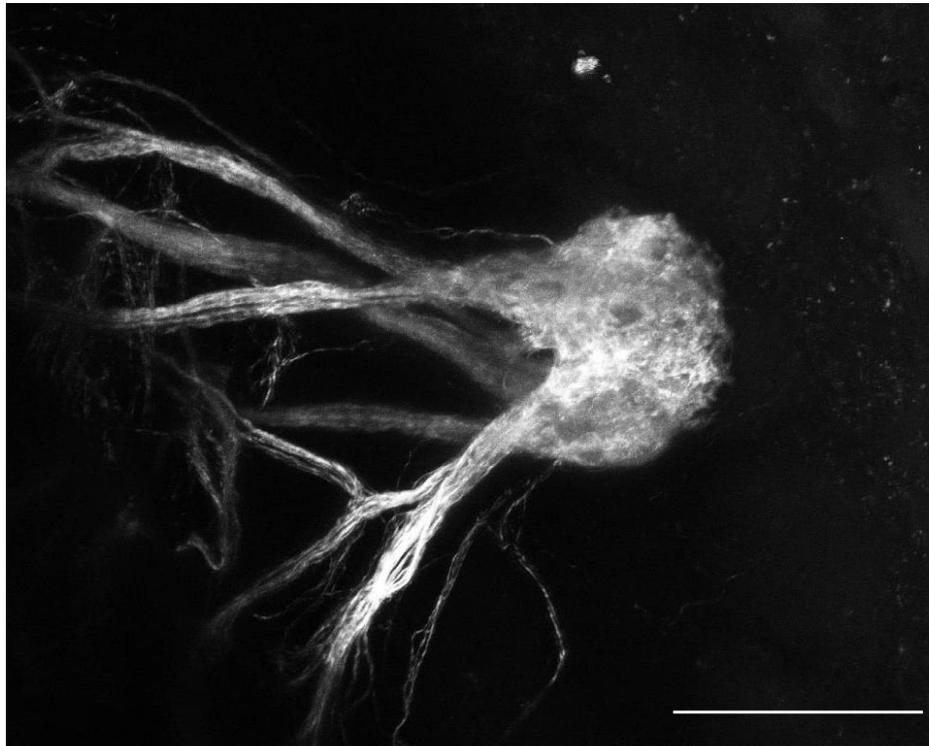

Figure 2.7 SR1-IRES-tauGFP glomerulus

Two-photon microscope image of SR1-IRES-tauGFP PD21 mouse shows a lateral glomerulus. This image shows how the axon bundles project and form the characteristic homogeneous, round structure of a glomerulus. This image was reconstructed from z-stacks images with intrinsic fluorescence of GFP-expressing OSNs. Scale bar: 250 μ m.

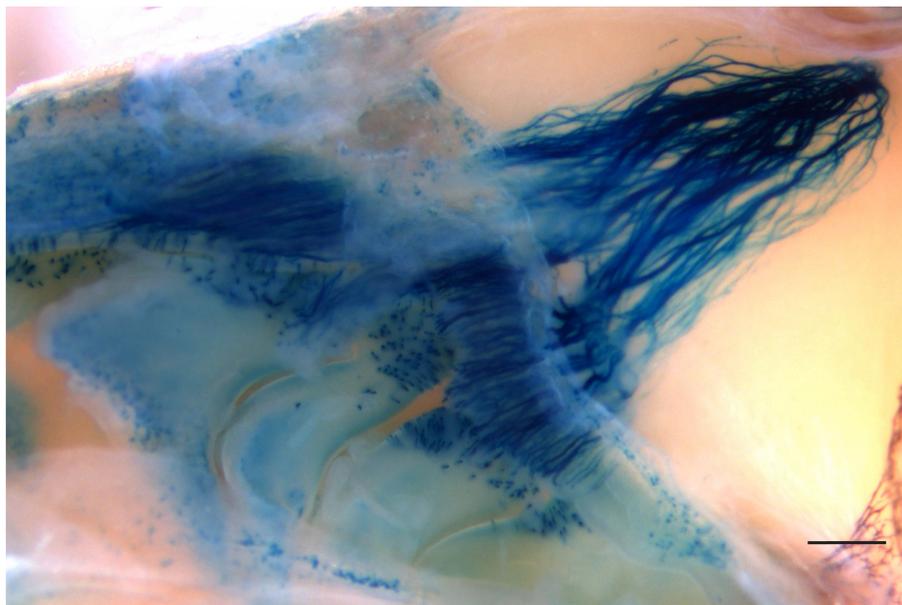

Figure 2.8 Axonal projection of M71

Sagittal whole mount of M71-IRES-taulacZ PD21 shows the projection of M71-expressing OSNs to the olfactory bulb where they form one glomerulus per half-bulb. OSNs and axons were visualized by x-gal staining. Scale bar: 500 μ m.

Nearly quarter of a century after the discovery of the ORs the mechanisms that govern this precise axonal wiring are not fully understood. In recent years several factors that modify the glomerular position or axonal wiring in general have been discovered. For instance several knockouts in parts of the signal transduction cascade in mice have interesting effects on axonal wiring. Silencing of an OR by mutating the N terminal G protein binding site with a RDY mutant abolishes glomerular formation in rat I7-expressing OSNs in transgenic mice (Imai et al., 2006). This phenotype can be rescued with the expression of a constitutively active $G_{\alpha s}$ subunit (caGs). CaGs does not need to bind to the GPCR to initiate a signal transduction event and thus can maintain cAMP level even with a silent OR. The most prominent effects are reported for a knockout of AC3, resulting in a disturbed axon wiring. For all OSNs tested in an AC3-deficient background, the axonal wiring was found to be perturbed leading to the formation of ectopic glomeruli or abolishing the formation of glomeruli even when the axons project to the correct position (Zou et al., 2007). An AC3 deletion also perturbs the fine axon sorting in the glomerular layer (Chesler et al., 2007). The same article also shows that even the ectopic expression of $G_{\alpha olf}$ can be sufficient to establish a unique glomerular position. A knockout of $\beta 3GnT2$, which modifies AC3, leads to defects in axonal wiring (Henion et al., 2011). Surprisingly a knockout of CNG still leads to fairly normal axonal wiring in the OB even though the depolarization as a result of the signal transduction cascade is abolished (Lin et al., 2000). However a conditional knockout of OCNC1 (a subunit of the CNG, now known as *Cnga2*) leads to miswiring and multiple, ectopic glomeruli for M72 neurons (Zheng et al., 2000). In the OCNC1 knockout strain these nonfunctional OSNs die due to the lack of function, however if combined with naris closure the non functional OSNs are not replaced (Zhao and Reed, 2001).

Another important factor for axonal wiring is the OR sequence itself. Several articles have reported on the effect of replacing the OR genetic sequence with another and the consequences for axonal wiring. The first study in that regard was published in 1996 and showed that by replacing the P2 sequence with M71, labeled axons form glomeruli but at a different

position (Mombaerts et al., 1996). This gene replacement experiment was performed next with P3, M71 or M50 into the P2 locus: in each case, the axons still form glomeruli but at a different position (Wang et al. 1998). These positions are different from the P2 position and the normal position of the replacing OR, mostly somewhere in between the two positions (Mombaerts et al., 1996; Wang et al., 1998). Only when the OR sequence is closely related to the native OR sequence, for example in the case of M71 and M72, it is possible to shift the glomerular position completely to the position characteristic for the replacing OR (Feinstein and Mombaerts, 2004). But in most cases the OSNs with a replaced OR form glomeruli at novel position in the OB, as shown for the rat I7 in M71 (Bozza et al., 2002) and M72 in S50 (Bozza et al., 2009; Zhang et al., 2012). Even a single nucleotide substitution can shift glomerular position (Feinstein and Mombaerts, 2004). A non-olfactory GPCRs can substitute as an OR when put in an OR locus: the β 2 adrenergic receptor (β 2AR) expressed from the M71 locus can support the formation of glomeruli (Feinstein et al., 2004, Omura et al., 2014). Another interesting effect was shown with an intricate downregulation of M71 expression. In this gene-targeted strain the M71 sequence was flanked by fluorescent marker proteins and behind an IRES site. Genes downstream of an IRES site are expressed less well. This so-called hypomorph shows an anterior shift in glomerular position (Feinstein et al., 2004) even though the OR sequence is identical. All gene replacements described have the functional responsiveness of the replacing OR (Bozza et al., 2002) but the hypomorph has a reduced responsiveness compared to M71-expressing OSNs (Zhang et al., 2012). Several transgenic strains expressing ORs have been established, either forming glomeruli in the same position as the OSN populations that normally express these ORs (Vassalli et al., 2002, Rothman et al., 2005) or not (Nakatani et al., 2003, Miyamichi et al., 2005). Modification of the homeodomains upstream of M71 show that axonal wiring can be shifted or perturbed even if the OR is still expressed (Rothman et al., 2005). Accordingly the O/E proteins, which bind Olf1 sites found in promoter regions of genes in OSN development such as OMP, are important for correct axonal wiring (Wang, 2004).

Surprisingly mitral cells, which form the first synapse with the axons of OSNs in the glomerular layer, are not important for glomerular formation (Royal et al., 2002). Even with an aberrant organization of the postsynaptic mitral cells in the olfactory bulb, P2-IRES-*tau*lacZ-expressing OSNs project to their typical position. Likewise the GABAergic interneurons are not necessary for glomerular formation (Bulfone et al., 1998). However it is important to note that the glomeruli of a single OSNs population are functionally connected within the OB. The activity in a glomerulus does not only inhibit their neighboring glomeruli via lateral inhibition fine tuning their postsynaptic mitral/tufted cells (Tan et al., 2010) but also inhibit their corresponding glomerulus in the same bulb (Lodovichi et al., 2003). It has been shown for M71-expressing OSNs that their glomerulus is bilaterally connected via the anterior olfactory nucleus pars externa (Yan et al., 2008).

One further explanation for the precise and homogeneous axonal wiring is found in the diverse expression of cell adhesion molecules, marker proteins for regions of the epithelium and cell surface molecules. Similarly, the olfactory cell adhesion molecule (OCAM) expressed in OSNs in the ventral region of the MOE, which project to the ventral region of the OB. OCAM is however not needed for axonal wiring per se, but for establishing a fine axonal sorting and subcompartments within a glomerulus (Walz et al., 2006). Other molecules, like neurotrophin-3 (NT-3) and transient receptor potential M 5 (TrpM5), are also differentially expressed by OSNs, but the role of these molecules is not resolved (Rolen et al., 2014). The protein Big-2 is differentially expressed in the OB and is reported to mediate olfactory axon convergence (Kaneko-Goto et al., 2008). Another cell adhesion molecule called Gicerin is differentially expressed in the OB at E17.5 (Williams et al., 2007). Again its role remains to be determined.

Several prominent cell adhesion molecule systems are also expressed in the olfactory system and play an important role in axonal wiring. For example the roundabout (Robo)/Slit complex is important in early axonal wiring. If Robo 1, which is expressed in ensheathing cells, is deleted, the axons are stopped from reaching the dorsal OB and axonal wiring is perturbed. However this

effect was only shown in transgenic mice, expressing β 2AR from the MOR23 promoter (Aoki et al., 2013). In Robo-2 or Slit-1 knockout mice, OSNs residing in zone 1 do not project their axons to the dorsal bulb but form glomeruli in the ventral region of the bulb (Cho et al., 2007). In Robo-1 and Robo-2 double knockout embryos (E16-18) most OMP positive axons fail to reach the OB. However MOR256-17-expressing OSNs still form ectopic homogeneous glomeruli in Slit-1 and Slit-2 double knockout as well as in Robo-1 and Robo-2 double knock out mice at E18 (Nguyen-Ba-Charvet et al., 2008). These results show that Robo/Slit is an important but broadly applied factor in the dorsal/ventral axonal wiring in mouse.

Another factor in the dorsal/ventral patterning is the cell adhesion molecule Neuropilin 2 (Nrp2) and its repulsive ligand Semaphorin 3F (Sema3F). Nrp2 has been reported to be expressed in a gradient increasing in ventral direction and a knockout of Nrp2 will shift glomerular position dorsally (Takeuchi et al., 2010). Another study shows that a knockout of Nrp2 mostly influences OSNs expressed in the classical zone 4 of the MOE. In Nrp2 knockout mice, OSNs expressing MOR28 and I7 start forming multiple and partly ectopic glomeruli but this result was shown with two mice (Takahashi et al., 2010).

As stated before, intact activity of OSNs is an important factor for the formation of homogeneous glomeruli. For example, an overexpression of the inward rectifying potassium channel Kir2.1 diminishes the excitability of OSNs and severely disrupt glomerular formation (Yu et al., 2004). Two pairs of cell adhesion molecules play a crucial role in the fine sorting of the axons and maintaining homogeneity: Kirrel2/Kirrel3 (self adhesive) and Eph-A5/Ephrin-A5 (repulsive effect) are activity dependently expressed and support fine axonal sorting in glomerulus (Serizawa et al., 2006). A knockout of Ephrin-A3 and Ephrin-A5 shifts glomeruli of OSNs expressing SR1 and P2 to a more posterior position in the OB (Cutforth et al., 2003).

The last group of differentially expressed molecules, and least studied, is cell surface carbohydrates (glycans). For example, the cell surface carbohydrates UEA and DBA are expressed in conserved patterns in the

MOB. However these patterns are not correlated with glomeruli of OSNs expressing M71 or P2 (Lipscomb et al., 2003). UEA is expressed in subset of cells in MOE forming several small microglomeruli, which appear to be a different population to AOE glomeruli and OR glomeruli (Lipscomb et al., 2002b). The lectin DBA is differentially expressed in glomeruli and can be detected with different intensities in the glomerular layer of the bulb. But there are OMP-negative and DBA-positive axons contributing to these glomeruli (Lipscomb et al., 2002a). Finally a knockout of the β 3GnT1, which regulates extension of lactoseamines in glycans, results in cell death of OSNs and impaired wiring (Henion et al., 2005).

2.8 Neuropilin-1

The cell adhesion molecule Neuropilin 1 (Nrp1) is for one of the most promising contenders for establishing the anterior/posterior glomerular position of glomeruli in the MOB. Nrp1 is differentially expressed in the MOE and MOB (Pasterkamp et al., 1998). OCAM and Neuropilin-1 form distinct and different patterns in the MOB (Nagao et al., 2010). Nrp1 is also expressed in sensory neurons in the Grüneberg ganglion. It has been shown that it is needed for axonal wiring (Matsuo et al., 2012). Nrp1 forms a complex with Plexin A1 and detects the repulsive ligand Semaphorin 3A (Sema3A). This complex is sufficient for Sema3A detection, but the expression level of Nrp1 is increased in the presence of Plexin A1 (Takahashi et al., 1999). The soluble Sema3A has been shown to be important for axon sorting. It is expressed in a spiral pattern around the rostro-caudal axis in the MOB. Nrp1 is expressed in a contrary pattern (Schwartz et al., 2000). A knockout of Sema3A perturbs axonal wiring of P2-expressing OSNs. Lack of Sema3A results in formation of multiple glomeruli and their characteristic position is not maintained (Schwartz et al., 2004). Expression of Sema3A is involved in reducing cAMP levels in vitro, giving a clue about the relation between the signal transduction cascade and the expression of cell adhesion molecules, but these results have yet to be confirmed in OSNs (Shelly et al., 2011). A popular theory has emerged in the last years that a gradient of Nrp1 is the sole determinant of the

glomerular position along the anterior-posterior axis, while the finer sorting is activity-dependent mediated by fine sorting through Kirrel2/EphA5 and Kirrel3/ephrin-A5 (Imai and Sakano, 2008). A conditional knockout of Nrp1 initiated from a transgene expressed rat I7 OR from mouse MOR23 promoter shifts glomerular position more anteriorly, whereas expression of caGs in these OSNs shifts the glomeruli more posteriorly (Imai et al., 2009). The proposed model is that the basal activity of an OR in development mediated by the $G_{\alpha s}$ subunit is involved in regulating cAMP levels in a gradient manner (Nakashima et al., 2013). However this explanation cannot explain all the results of the AC3 knockout (Zou et al., 2007), which has a distinct phenotype of ectopic glomerular formation for the M71- or M72-expressing OSNs. In addition, recent studies showed that OSNs expressing M71 and MOR23 have similar spontaneous activity (Connelly et al., 2013) although the glomerular position is very different in the MOB (Col et al., 2007).

3 Materials

3.1 Animals

Most strains used in this thesis were generated by the lab of Dr. Peter Mombaerts using the method of gene targeting described in (Mombaerts et al., 1996), where a target sequence in the genome is replaced with a modified sequence by homologous recombination in mouse embryonic stem cells. Most strains contain an internal ribosomal entry site (IRES). This sequence originates from the encephalomyocarditis virus and enables coexpression of two genes from a single mRNA transcript (Kaminski et al., 1990). This IRES is used to coexpress a reporter gene, such as GFP, under the same promoter simultaneously with the gene of interest, such as an OR.

Mice were maintained in specified pathogen-free conditions in individually ventilated cages of the Tecniplast green line (Tecniplast, Italy). Mice received *ad libitum* gamma-irradiated ssniff V1124-727 (ssniff, Soest, Germany). Nesting, bedding, and enrichment were provided as nestpak, Datesand Grade 6 (Datesand, Manchester, United Kingdom). Mouse experiments were carried out in accordance with the German Animal Welfare Act, European Communities Council Directive 2010/63/EU, and the institutional ethical and animal welfare guidelines of the Max Planck Institute of Biophysics and the Max Planck Research Unit for Neurogenetics. Approval came from the Regierungspräsidium Darmstadt, and the Veterinäramt of the city of Frankfurt.

Table 3.1 List of strains

Strain name	Reference	Availability
P3-IRES-tauGFP	Feinstein and Mombaerts, 2004,	http://jaxmice.jax.org/strain/006684
M71-IRES-tauGFP	Bozza et al., 2002, Feinstein et al., 2004;	http://jaxmice.jax.org/strain/006676
mOR37C-IRES-tauGFP	Strotmann et al., 2000,	http://jaxmice.jax.org/strain/006641
S50-IRES-tauGFP	Bozza et al., 2009,	http://jaxmice.jax.org/strain/006712
MOR23-IRES-tauGFP	Vassalli et al., 2002,	http://jaxmice.jax.org/strain/006643
M72-IRES-tauGFP	Potter et al., 2001,	http://jaxmice.jax.org/strain/006678
M50-IRES-GFP-IRES-tauLacZ	Feinstein and Mombaerts, 2004,	http://jaxmice.jax.org/strain/006686
mI7-IRES-tauGFP	Bozza et al., 2002,	http://jaxmice.jax.org/strain/006664
P2-IRES-tauGFP	Feinstein and Mombaerts, 2004,	http://jaxmice.jax.org/strain/006669
SR1-IRES-tauGFP	Fuss et al., 2013,	http://jaxmice.jax.org/strain/006711
MOR256-17-IRES-tauGFP	Khan et al., 2011,	http://jaxmice.jax.org/strain/007762
β 2AR \rightarrow M71-IRES-tauGFP	Omura et al., 2014,	http://jaxmice.jax.org/strain/006734
RFP \rightarrow M71iM71iGFP	Feinstein et al., 2004,	http://jaxmice.jax.org/strain/006689

Nrp-1-flox/J		http://jaxmice.jax.org/strain/005247
Npn1-5247	Gu et al., 2003,	same as Nrp-1 ^{fllox} but directly obtained from Jackson Lab JR#5247
I7(WT)-Cre	Imai et al., 2006,	RBRC02932
ROSA-STOP-tauLacZ		unpublished
OMP-Cre	Li et al., 2004,	http://jaxmice.jax.org/strain/006668.html
OMP-tauSTOPlacZ		unpublished
R26-tauGFP		Unpublished, Uli Boehm, Hamburg

3.2 Chemicals

3.2.1 Molecular Biology

Chemicals	Provider
Plates	Mombaerts lab
Carbenicilin	Sigma-Aldrich, St. Louis MO, USA
Primers	ThermoFisher Scientific, Waltham, MA, USA & eurofins MWG, Ebersberg
Restriction enzymes & Buffers (EcoRI, NcoI, PaeI, AclI, HindIII, KpnI, PmeI, NotI, XhoI, KpnI, SacI, SacI-HF, SacII, XbaI, EagI)	NEB, Ipswich, MA, USA
Vectors pBluescript K+	Vectors Agilent Technologies, Waghäusel-Wiesental
pGEMT easy vector	Promega, Madison, WI, USA
T4 Ligase & Buffer	Promega, Madison, WI, USA
Sequencing service	QIAGEN, Hilden
QIAprep Spin Mini Prep	QIAGEN, Hilden
QIAfilter Plasmid Midi Kit	QIAGEN, Hilden
QIAGEN Large-construct Kit	QIAGEN, Hilden
QIAquick Gel extraction Kit	QIAGEN, Hilden
Competent cells dH5α XL2-Blue Ultracompetent cells MAX efficiency DH5a	Competend cells Life Technologies GmbH, Darmstadt Agilent Technologies, Waghäusel-Wiesental Life Technologies GmbH, Darmstadt
SOC Medium	Life Technologies GmbH, Darmstadt
Hyperladder II	Bioline, Luckerwalde
Phusion Polymerase	Finnzyme, Finland and ThermoFisher Scientific, Waltham, MA, USA
Gel extraction kit QIEX	Gel extraction kit QIEX
2-log DNA ladder	NEB, Ipswich MA, USA
Ligation kit long	Takara Bio Inc, Shiga, Japan
Isopropanol	Sigma-Aldrich, St. Louis, MO, USA
Ethanol	Sigma-Aldrich, St. Louis, MO, USA
CIP	NEB, Ipswich MA, USA

LB media and plates were provided by the institute. They were made according to the following recipe (Table 3.2).

Table 3.2 MPI recipes

LB Medium	Agar Plates
10 g Tryptone (Fluka, 95039-1KG-F)	LB Broth with agar (SIGMA L7025-500TAB) 1Tablet per 50 ml
5 g Yeast Extact (Fluka, 70161-500G)	1 ml Carbenicillin (25 mg/ml) per 500 ml
10 g NaCl (Roth, 3957.5)	
In 1L H ₂ O	

3.2.2 Genotyping

Material	Provider
Taq Hot Start	Takara Bio Inc, Shiga, Japan
Primer	Sigma-Aldrich, St. Louis MO, USA
dNTPS	Takara Bio Inc, Shiga, Japan
10x Reaction Buffer	Takara Bio Inc, Shiga, Japan
Proteinase K	Bioline, Luckerwalde
Digestion buffer	Peqlab, Erlangen
Agarose	Carl Roth + Co. KG, Karlsruhe
Ethidium Bromide (EtBR)	Carl Roth + Co. KG, Karlsruhe
Standard	NEB, Ipswich, MA, USA
Tris Borate EDTA (TBE) 10x Stock	Carl Roth + Co. KG, Karlsruhe
Tris Acetate EDTA (TAE) 50x Stock	Carl Roth + Co. KG, Karlsruhe
Loading dye	Life Technologies GmbH, Darmstadt

3.2.3 Antibody staining

Material	Provider
Normal Donkey Serum	Jackson Immuno Research, Newmarket Suffolk, UK
Normal Goat Serum	Jackson Immuno Research, Newmarket Suffolk, UK
Bovine Serum Albumin	Sigma-Aldrich, St. Louis, MO, USA
Triton	Sigma-Aldrich, St. Louis, MO, USA
Parafilm	Parafilm, Oshkosh, WI, USA
Citrate Buffer	Sigma-Aldrich, St. Louis MO, USA
DAPI	Life Technologies GmbH, Darmstadt
Moviol	Calbiochem, EMD Chemicals, San Diego, CA, USA

3.2.4 Antibodies

Primary Antibody	Recommended concentration	Provider (serial number)
Chicken anti GFP	1:500	Abcam (ab13970)
Chicken anti β -gal	1:1000	Abcam (ab9361)
Chicken anti M71	1:500-1:3000	Abcam (ab65573)
Rabbit anti dsRED	1:250	Clontech (632496)
Rabbit anti Neuropilin1	1:200	Abcam (ab25998)
Goat anti Neuropilin1	1:100	R&D Systems (AF566)

Secondary Antibody	Recommended concentration	Provider (serial number)
ALEXA 488 Goat anti Chicken	1:500	Invitrogen (A11039)
ALEXA 546 Donkey anti Chicken	1:500	Invitrogen
Rhodamin Red-X (RRX) Donkey anti Rabbit	1:500	Jackson (711-295-152)
Fluorescein (FITC) Donkey anti Chicken	1:500	Jackson (703-545-155)
Cy5 Donkey anti Goat	1:500/1:200	Jackson (705-175-147)
ALEXA 546 Donkey anti Goat	1:500	Invitrogen (A11056)
ALEXA 488 Goat anti Chicken	1:500	Invitrogen (A11039)
ALEXA 488 Goat anti Rabbit	1:500	Invitrogen (A11034)
ALEXA 546 Goat anti Rabbit	1:500	Invitrogen (A11010)
DyLight 488 Goat anti Chicken	1:500	Bethyl Laboratories (A30-206D2)
ALEXA 555 Donkey anti Rabbit	1:500	Invitrogen (A31572)

3.2.5 X-gal staining

Material	Provider
5-bromo-4-chloro-3-indolyl- β -D-galactopyranoside (x-gal)	Roche Diagnostics Corporation, Indianapolis, IN, USA
Dimethylformamide (DMF)	Sigma-Aldrich, St. Louis, MO, USA
Magnesium Chloride (MgCl ₂)	Sigma-Aldrich, St. Louis, MO, USA
ethylene glycol tetraacetic acid (EGTA)	Sigma-Aldrich, St. Louis, MO, USA
Na deoxycholate	Sigma-Aldrich, St. Louis, MO, USA
Kalium hexacyanoferrate II &III	Sigma-Aldrich, St. Louis, MO, USA
Igelpal CA-630	Sigma-Aldrich, St. Louis, MO, USA

3.2.6 X-gal staining buffer

Buffer A	Buffer B	Buffer C
100 mM PBS (pH 7.4)	100 mM PBS (pH 7.4)	5 mM
2 mM MgCl ₂	2 mM MgCl ₂	5 mM
5 mM EGTA	0.01% Na deoxycholate	1 mg/ml X-gal in DMF
	0.02% IGEPAL CA-630	In Buffer B

3.2.7 Perfusion

Material	Provider
Paraformaldehyde	Sigma-Aldrich, St. Louis, MO, USA & Merck, Darmstadt
Phosphate Buffered Saline	Sigma-Aldrich, St. Louis, MO, USA
Sucrose	Sigma-Aldrich, St. Louis, MO, USA
Ethylenediaminetetraacetic acid (EDTA)	Sigma-Aldrich, St. Louis, MO, USA
NaOH	Sigma-Aldrich, St. Louis, MO, USA
NaCl	B.Braun, Melsungen
10% Ketamin	Medistar Arzneimittelvertrieb GmbH, Ascheberg
Xylazin	bela-pharm, Vechta
Xylavet	cp-pharma, Burgdorf
Scissors	fine science tools, Heidelberg
Granulated dry ice	Linde AG, Muenchen

3.3 Consumables

Consumables	Provider
Falcon Tubes 15 & 50 ml	ThermoFisher Scientific, Waltham, MA, USA
Glass Ware	Simax, Sazava, Tschechische Republik & VWR, Darmstadt & Druan, Wertheim
Gloves blue & white	Ansell, Brüssel, Belgium & VWR, Darmstadt
Tissues	Kimberly-Clark, Mainz & VWR, Darmstadt
Pasteur Pipette	VWR, Darmstadt &
Big pipettes (5 ml, 10 ml, 25 & 50 ml)	Biosphere/SARSTEDT, Nuernbrecht
Pipette tips (2.5 µl, 20 µl, 200 µl & 1 ml)	Biosphere/SARSTEDT, Nuernbrecht
Needles	Henry Schein, Langen & B.Braun, Melsungen
Small petri dish	ThermoFisher Scientific, Waltham, MA, USA
Syringes	B.Braun, Melsungen
Filters	ThermoFisher Scientific, Waltham, MA, USA
Eppendorf tubes	Eppendorf, Hamburg
Tail tubes	Simport, Beloeil QC, Canada
PCR tubes+ caps	Brand, Wertheim
pH Standards	Merck, Darmstadt
Spatulas	VWR, Darmstadt
Gasburner	Fischer Scientific GmbH, Nidderau

Sectioning

Material	Provider
Coverslips	Menzel, Braunschweig
Slides	ThermoFisher Scientific, Waltham, MA, USA

3.4 Equipment

Equipment	Provider
Cryostat	Leica Biosystems, Wetzlar
ddH ₂ O Filter Millipore Advantage	Millipore, Billerica MA, USA
PCR Machines/Thermocycler	Applied Biosystems, Darmstadt
Mac	
pH Meter	Eutech Instruments, Landsmeer, Netherlands
Windows PC	
-Pipett Boy Pipetus	Hirschmann Laborgeraete, Eberstadt
-Zentrifuge: Table Sorvall RC6 plus	Eppendorf, Hamburg), ThermoFisher Scientific, Waltham, MA, USA
Gel Doc	Peqlab, Erlangen
Gel Chambers	BioRad, Hercules CA
Incubator 37°C	ThermoFisher Scientific, Waltham, MA, USA
Shaker 37°C	Infors HT, Einsbach
Vacuum pump	Eppendorf, Hamburg
Autoclave	Systec, Wettenberg
Balances	Sartorius, Goettingen
Shaker	Stuart, Staffordshire, UK
Heater	Heidolph Instruments, Schwabach
Stirrer	Heidolph Instruments, Schwabach
Fridge	Liebherr, Biberach an der Riss
Freezer: -80°C -20°C	ThermoFisher Scientific, Waltham, MA, USA, Gram, Sarstedt & Liebherr, Biberach an der Riss
Nanodrop	Peqlab, Erlangen
Waterbath	GFLN, Burgwedel
Quiacube	QIAGEN, Hilden

3.5 Microscopes

Microscope	Provider
LSM 510	Carl Zeiss, Wetzlar
LSM 710	Carl Zeiss, Wetzlar
Aperio Scanscope FI	Aperio (Leica), Wetzlar
NIKON SMZ25	Nikon GmbH, Duesseldorf
Two photon microscope Mai tai	Newport-Spectra-Physics, Darmstadt

3.6 Software

Software	Provider
Prism	Graphpad Software Inc., La Jolla, CA, USA
Excel	Microsoft
Word	Microsoft
ZEN	Carl Zeiss GmbH, Jena
Fiji	Open source software
Matlab	Mathworks, Ismaning
Scanscope Viewer	Leica Biosystems, Wetzlar
Papers	Mekentosj B.V., Dordrecht, Netherlands

3.7 Sequences

4 Methods

4.1 Molecular work

This chapter describes the methods used for molecular work, the modification of the deoxyribonucleic acid (DNA), the generation of new plasmids and the amplification of DNA regions of interest.

4.1.1 Polymerase chain reaction (PCR)

In the thermocycler the hydrogen bonds of the double-stranded DNA are broken, the primers anneal at the complementary position and Taq DNA polymerase uses these primers as starting points to complement the single DNA strands to double strands again. This process is repeated for several cycles while the original DNA and the new synthesized strands serve as template for DNA synthesis, doubling the DNA sequence defined by the primers in each cycle.

PCR was performed to genotype the strains using the protocols described in Chapter 4.8.2 using the standard protocols there. Also PCR was used to generate PCR fragments for targeting vector construction as described in Chapter 4.1.8.

4.1.2 Gel electrophoresis

Gel electrophoresis is a method to separate DNA molecules by their size. To that end, the DNA molecules, mostly from PCR reactions or restricted plasmids, are loaded with the loading dye onto agarose gels with 3 μ l Ethidium Bromide (EtBr) per 100 ml gel. EtBr intercalates with double-stranded DNA and shows fluorescence in the UV spectrum (302 nm). The percentage of agarose varies for the different experiments and ranges from 1 to 1.5 % (w/v). After applying a voltage, normally between 80 to 120 V, the negatively charged DNA molecules migrate toward the positive pole. Due to the interconnections that the agarose forms after heating, larger molecules are traveling slower through the gel. A standard with known DNA sizes is loaded onto the gel for reference.

4.1.3 Restriction enzyme digestion

To generate the plasmids described in Chapter 5 and to arrange the DNA sequences restriction endonucleases were used. These enzymes recognize specific sequences of four to eight base pairs of DNA and cleave after a specific nucleotide of that sequence. All endonucleases and buffers were obtained from New England Biolabs (NEB). Occasionally the restricted DNA molecule is additionally treated with CIP to remove phosphate from restriction sites and prevent reannealing. The restriction reaction (Table 4.1) is incubated at 37°C for 4 h or overnight. If necessary, the sample is incubated with 1 µl of CIP at 37°C for 10 min afterwards. The mix is loaded on a 1% ultrapure agarose gel and run with 80 V. The DNA is cut from the gel and purified using Qiagen Gel Extraction Kit.

Table 4.1 Restriction mixture

	µl
DNA (5 µg or 10 µg)	X
Buffer	2
BSA (depending of enzyme)	0.2
H ₂ O	Fill up to 19 (18 if double digestion)
Enzyme(s)	1
Total	20

4.1.4 Ligation

To insert the restricted and cleaned DNA fragments into a plasmid vector a ligation reaction is set up. For each insert and vector several concentrations for the insert are tested. The mixture is incubated at 4°C overnight or at 16°C for 5 h. The ligated mixture is used for transformation. The ligation kits used were from TaKaRa (Shiga, Japan) for ligation of long fragments or from Promega (Madison, WI, USA) for assembling the insert cassette.

Table 4.2 Ligation mixture

	µl	µl	µl	µl
Vector	1	1	1	1
Insert	1.5	5	9	0
Buffer	2	2	2	2
Ligase	1	1	1	1
Water	14.5	11	7	16
Total volume	20	20	20	20

4.1.5 Transformation

This protocol was used to transform the bacteria with the plasmid generated for this thesis. Using bacteria culture is a fast way to amplify plasmids for further usage, using the antibiotic resistance provided by the plasmid to foster the growth of the transformed culture.

- Remove required number of LB-Carb plates from 4°C and warm in 37°C incubator.
- Leave open for 10-15 min to dry the plates (not too dry!)
- Thaw competent cells on ice slowly, over 5-10 min.
- Label Eppendorf tubes and place them on ice.
- Dispense 50 µl of competent cells to labelled Eppendorf tubes gently.
- Add 3 µl ligation reaction mixture (see Ligation protocol).
- Incubate the cells-ligation mixture on ice for 30 min.
- Heat shock cells for 45 sec at 42°C in the water bath.
- Place tubes immediately on ice.
- Leave the cells to rest for 10 min.
- Add 500 µl SOC medium to each tube (Always 10x of the competent cell volume) and leave for another 10 min on ice.
- Incubate on rotating platform for two hours at 37°C.
- Add 20 µl of X-Gal directly onto plate and spread evenly with plastic spreads. (Only necessary for first insert)
- Put plates back in 37°C incubator and leave the plates exposed to dry for 10-30 min.
- Remove the competent cells from rotating platform and begin spreading.
- Resuspend the cells gently by pipetting and transfer 300 µl directly onto plate.
- Spread gently and evenly with glass pipettes.
- Incubate plates at 37°C overnight. Remove the plates to RT or 4°C in the morning.

4.1.6 DNA extraction from colonies

This chapter describes the protocols used to seed a culture with the transformed bacteria and to extract the plasmid from it after growth. Two sizes of cultures were used: a 20 ml (mini) and a 200 ml (midi). The 20 ml culture is used to verify the correct sequence of the plasmid and the 200 ml is used to obtain larger volume of plasmid vector for further processing. To extract the plasmid from the cultures the Qiagen Kits for Mini and Midi Prep are used. For Mini Prep the extraction is done both manually as well as using the Qiacube.

Colonies are picked from agar plates with sterile pipette tips. The tip is then inserted in LB medium with Carbenicillin with final concentration of 50 µg/ml. The seeded culture is kept overnight (16-20 h) at 37°C and 150 rpm. When the bacteria culture is grown overnight the plasmids are extracted using the protocols provided by the Qiagen kits.

Following either protocol the cultures are spun down in a centrifuge and the supernatant is removed leaving the bacteria pellet behind. Subsequently, buffers and filter syringes provided in the kit are used to break the cells open and filter out all other molecules and organelles. The plasmids are then cleaned with ethanol and suspended in TE buffer for storage.

4.1.7 Sequencing

To verify the success of a ligation after preliminary testing with PCR or restriction enzyme digestion, plasmids are sequenced with corresponding primers. Targeted sequences are amplified similar to a PCR. However a proportion of the nucleotides used for sequencing is labeled and terminates the annealing reaction. Each of the four nucleotides is labeled differently. By measuring the length of the terminated fragment and knowing the label for each nucleotide the sequence of the template can be determined. The sequencing service of Qiagen (Hilden) was used. Sequencing results were generated as digital files.

4.1.8 Generating gene-targeting vectors

To generate the gene-targeting vectors for Chapter 5 multiple restrictions and ligations were needed using the techniques described in this chapter. The flowcharts illustrate the steps taken for generation of the final targeting vector.

For the insertion cassette a polylinker of nucleotides was generated containing SacI, Ascl, EcoRI, NcoI, PaeI Ascl and KpnI as restriction sites (ThermoFisher). This linker was inserted in pBluescript K+ Vector (Agilent Technologies). Afterwards the other sequences were ligated into the vector (Figure 4.1) step by step. The caGs (constitutively active G-protein subunit s) sequences were obtained from T. Imai (Imai et al., 2006) and amplified from the donated vector with primers designed to flank the gene by restriction sites for NcoI and PaeI. All other sequences were taken from stock plasmids available in the lab. The sequences were cut from the vector with restriction endonucleases (see Chapter 3.7.3), cut from gel and ligated in the target vector restricted with the same enzymes. Afterwards bacteria were transformed (see Chapter 4.1.5) with the ligated vector. After testing the correct insertion and transformation with PCR and sequencing the bacteria were amplified in a midi approach (see Chapter 4.1.6) and the plasmid vector was extracted and the process was repeated for the next step.

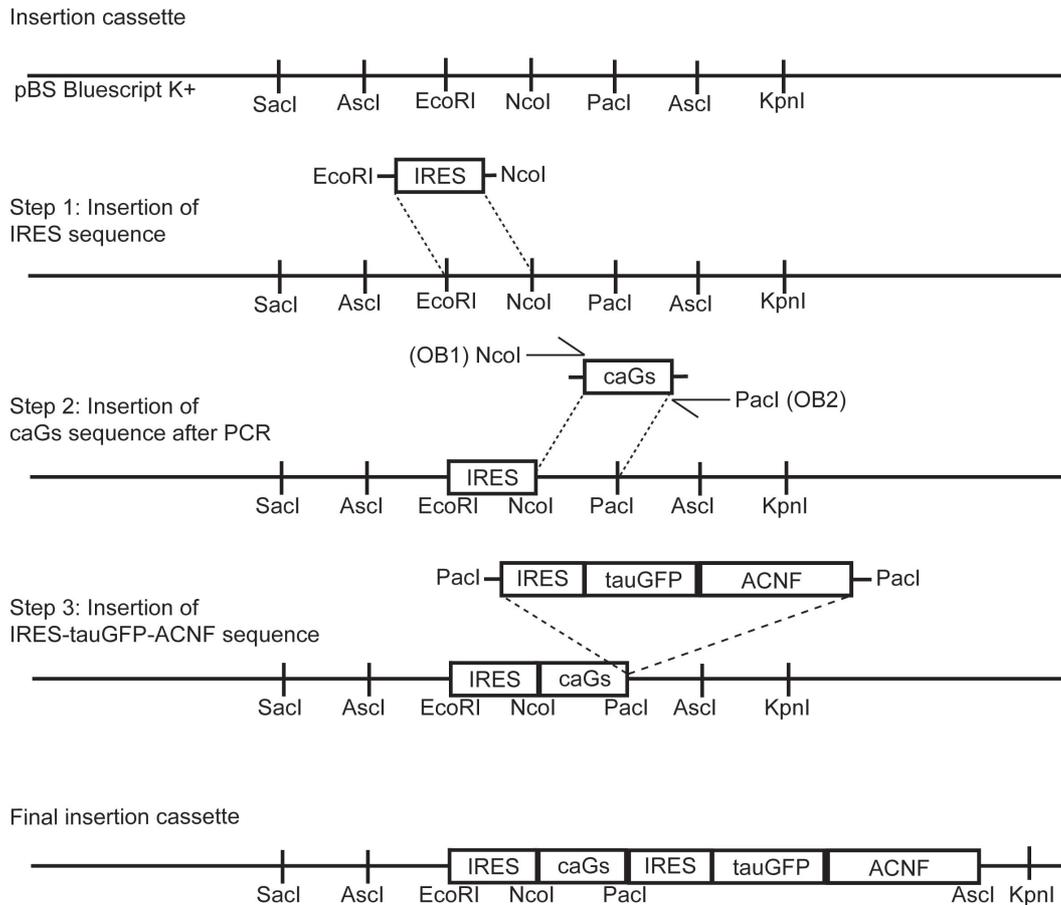

Figure 4.1 Generating the insertion cassette vector

In this figure the individual steps of restriction reactions and ligation constructing the insertion cassette vector are shown. The line represents the part of the plasmid vector containing the linker with all the restriction sites needed for the construction. Each insert was cut from the origin plasmid and ligated in the insertion cassette vector, except caGs, which was amplified from the original plasmid by PCR adding the necessary restriction sites (indicated by the arrow symbols in step 2).

At the same time the targeting vector on the basis of a pGEMT vector (Promega) was generated (Figure 4.2) by amplifying 4,532 base pairs (bp) in upstream direction from the end of M71 locus, called the left arm (la). Another arm was generated by amplifying 3,807 bp downstream of the M71 gene. Both PCRs used the Phusion Polymerase (Finnzyme through ThermoFisher) and were conducted with a M71 targeting available available in the lab. These two arms were inserted in the targeting vector and as a final step the insertion cassette generated in the other vector was cut and ligated in the targeting vector. The PmeI restriction site in the targeting vector is used for linearization of the vector prior to electroporation into ES cells.

Targeting vector

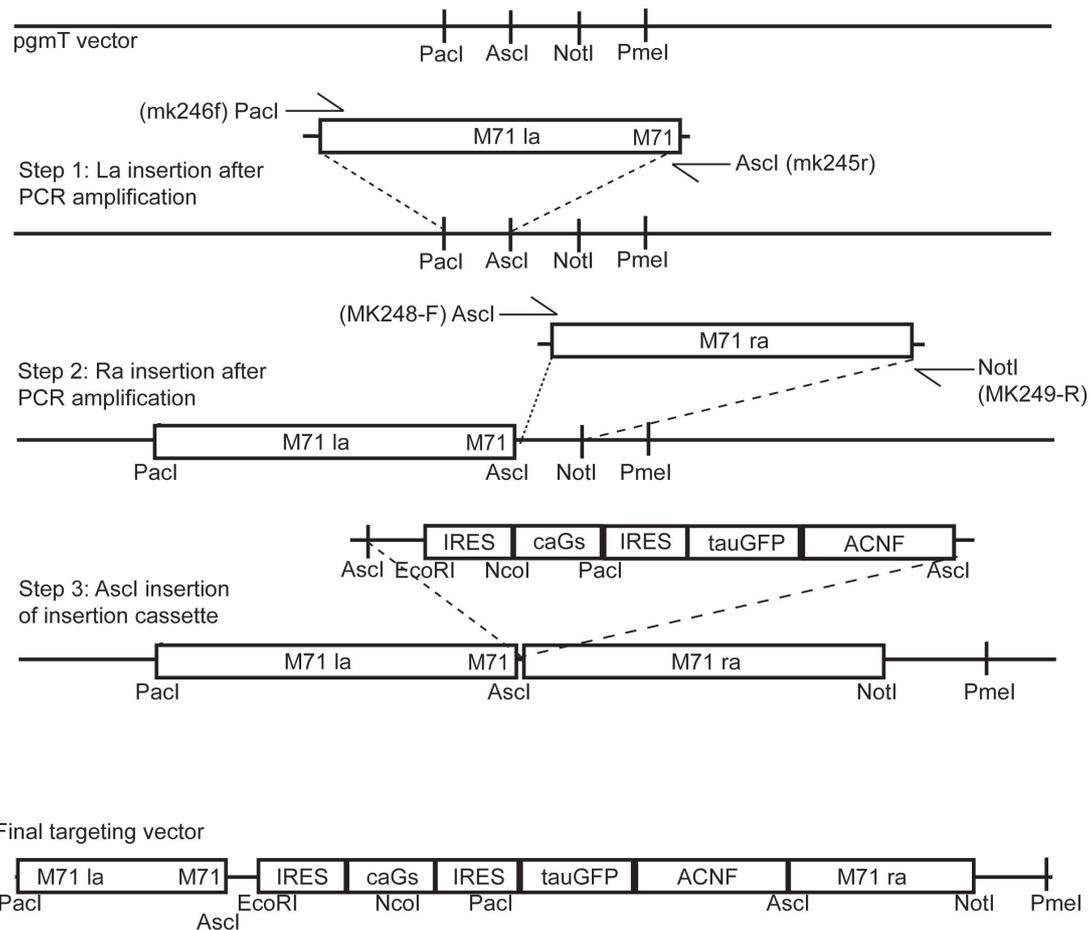

Figure 4.2 Generation of the gene-targeting vector

In this figure the individual steps of restriction reactions and ligation constructing the targeting vector are shown. The line represents the part of the plasmid vector containing the linker with all the restriction sites needed for the construction. The left and right arms of the targeting sequence were amplified for the M71 targeting vector with PCR adding the necessary restriction sites (indicated by the arrows). As a final step the insertion cassette was ligated into the targeting vector.

For a new construct the IRES-tauGFP sequences were replaced with IRES-tauCFP sequences but using the same method and concept.

4.2 Perfusion & Cryoprotection

Fixation of tissue is the first and most critical factor in microscopy. A strong fixation might prevent antibodies from reaching the intended targets and a weak fixation will not stop the degradation of the tissue post mortem. Likewise a good cryoprotection prevents tissue damage and preserves the anatomical structure of the tissue. The following protocol details the methods found most

suitable for the experiments in the mouse olfactory system reported in this thesis.

Mice were anesthetized with an intraperitoneal (i.p.) injection of 0.01ml/g anesthetic (0.25 ml 2% Rompun, 1.2 ml 10% Ketamin and 8.55 ml 0.9% NaCl) and after onset of narcosis fixed on a bench. Alcopads were used to mildly sterilize the fur and the skin was removed from the mouse abdomen. The ribcage was removed from sternum to throat. The left ventricle of the heart was pierced at the apex, parallel with the heart, with the syringe containing 1x PBS, then the right atrium was opened and the PBS was pumped into the ventricle. For PD21 or younger mice, 10 ml of PBS was used to wash out the blood. For PD70 mice 20 ml was used. Following the perfusion with PBS the mouse was perfused with the same volume of 4% PFA in 1x PBS (10 ml for PD21 mice).

Figure 4.3 Perfusion
Image of perfusion of a PD21 mouse. A needle is inserted in the left ventricle. The arrowhead points to right atrium.

After perfusion the head was removed with scissors. The mouse was tailed for genotyping. The skin, as well as eyes, ears, lower jaw and the palatine bone were removed. The head was immersed in 4% PFA in 1x PBS for 5 min in a vacuum pump and then incubated at 4°C for 2 h on a shaker. After the incubation PFA was exchanged for 0.45 M EDTA in 1x PBS and incubated over night on a shaker at 4°C (two nights for PD70 mice). EDTA was exchanged for 15% sucrose in 1x PBS and consecutively 30% sucrose in 1x PBS, always incubated over night at 4°C on a shaker (time doubled for PD70 mice).

After cryoprotection the head was trimmed and the teeth were removed. The caudal part of the head was cut in coronal direction (frontal plane) so it could be placed on the stage of the microtome for freezing. Afterwards the head was immersed in a cylinder of aluminum foil filled with O.C.T. The rostral tip was orientated to point to the center of the cylinder and the coronal base of the head was lowered to the bottom. Afterwards the cylinder was placed in granulated dry ice until O.C.T. was frozen. The cylinder with the frozen block was stored at -20°C for sectioning.

4.3 Sectioning

A consistent and reproducible method for sectioning is crucial for cell counts and reconstructions of three-dimensional objects from sections. All sections were collected from the fixed and frozen mice heads gained with the previously detailed method. The frozen samples were sectioned with a Leica CM3050 S cryostat at 12 µm thickness and -20°C. The sections were collected in sets of ten slides, alternating the slides for each section. In the end each slide contained 12 sections. The whole epithelium was sectioned in this manner and collected in sets of ten slides. The slides were stored at 4°C up to 48 h or at -80°C for longer storage.

4.4 Whole mount dissection (sagittal & dorsal)

While sections are ideal for the analysis of the cellular composition and quantitative estimates, whole mount preparations of the olfactory system are important for a general overview of the axon projections of the OB. Two different directions of the sections for the whole mounts were used: sagittal and dorsal. Each direction enables a different view on the OB and in concert they provide an overview of the axon projections for the strains reported in this thesis.

Mice were anesthetized with an i.p. injection of 0.01 ml/g anesthetic (0.25 ml 2% Rompun, 1.2 ml 10% Ketamin and 8.55 ml 0.9% NaCl). After onset of narcosis the mouse was decapitated with scissors. The mouse was tailed for genotyping. The skin, eyes, ears, lower jaw and the palatine bone were removed.

For the sagittal whole mount preparation the septum was cut from the ventral side with a scalpel and then the rest from the dorsal side. The halves were separated and the rest of the septum was removed.

For the dorsal whole mount preparation the skull was cut along the midline of the axial plane from the cauda over the ear holes to the eye sockets. Then the dorsal part was carefully removed with a forceps.

The heads were stored in 1x PBS at 4°C.

4.5 β -galactosidase staining

Some of the strains used express not a fluorescent reporter but β -galactosidase (β -gal). While fluorescent cells can be visualized directly with the microscope, β -gal tissue has to be stained and can only be observed afterwards with a bright field microscope. However, the reaction product is more stable. The protocol described in the following was used for visualization of OSNs expressing β -gal.

Sagittally or dorsally dissected samples were fixed with 4% PFA in 1x PBS for 10 min at 4°C. The PFA was removed and the samples were washed once with Buffer A at 4°C and then washed twice with Buffer A (Chapter 3.2.6) at

room temperature (RT) each for 5 min. Then the samples were incubated at RT in Buffer A on a shaker for 5 min. Afterwards the samples were incubated twice at RT in Buffer B for 5 min each. The samples were afterwards inserted into Buffer C and incubated for an hour or overnight at 37°C in the dark until a strong blue staining was visible. The samples were then washed in Buffer B and stored in 4% PFA in 1x PBS.

4.6 Fluorescent antibody staining

For antibody staining two different protocols were used. One protocol is optimized for the Neuropilin-1 antibody and one for all other antibodies used.

4.6.1 Neuropilin-1 protocol

- Drying sample slides from -80°C or 4°C with dryer (cold wind).
- Wash three times in 1x PBS at RT for 5 min each
- Blocking with 10% NDS in 1x PBS / 0.1 % Triton X 100 (PBS-T), 150µl per slide, cover with parafilm strip and incubation at RT for 1 h
- Remove excess blocking solution
- Primary antibody Goat α Nrp1 (1:100) (optional add Rabbit α dsRed 1:200 for double staining) and 3% BSA in PBS-T, 150 µl per slide, cover with parafilm strip and incubate over night (>16 h) at 4°C
- Wash three times in PBS-T at RT for 10 min each
- Secondary antibody Donkey α Goat Cy5 (1:250) (optional add Donkey α Rabbit Alexa 555 1:250 for double staining) and 3% BSA in PBS-T, 150 µl per slide, cover with parafilm strip and incubate for 1.5 h at RT
- Wash three times in PBS-T at RT for 10 min each
- Wash once PBS for 1 min at RT
- DAPI staining with 5 µl of 5 mg/ml DAPI stock solution to 150 ml PBS for 10 min at RT
- Wash the slides with PBS
- Mount slides with 60 µl Moviol and coverslip
- Let slides dry over night at RT

4.6.2 β -galactosidase staining protocol

- Drying sample slides from -80°C or 4°C with dryer (cold wind).
- Wash three times in 1x T-PBS at RT for 10 min each
- Blocking with 10% NDS in PBS-T, 150 μ l per slide, cover with parafilm strip and incubation at RT for 1h
- Remove excess blocking solution
- Primary antibody Chicken α LacZ (1:500) and 2% NDS in PBS-T, 150 μ l per slide, cover with parafilm strip and incubate over night (>16h) at 4°C
- Wash three times in PBS-T at RT for 10 min
- Secondary antibody Donkey α Chicken FITC (1:250) and 2% NDS in PBS-T, 150 μ l per slide, cover with parafilm strip and incubate for 1h at RT
- Wash three times in PBS at RT for 10 min
- DAPI staining with 5 μ l of 5 mg/ml DAPI stock solution to 150 ml PBS for 10 min at RT
- Wash the slides with PBS
- Mount slides with 60 μ l Moviol and coverslip
- Let slides dry over night at RT

4.7 Microscopy

Confocal imaging was performed using Zeiss LSM 510 and 710. For cell counting 25x water immersion lens and for glomerular volume measurements 40x water immersion lens was used. For confocal whole mount images 10x water immersion and 5x air lens were used. Whole slide scanning for overviews was performed with Aperio scanscope FL. Whole mount two photon images were taken with 40x water immersion lens using the Mai Tai system. Fluorescent whole mount images were also done using the NIKON SMZ25 stereomicroscope.

4.8 Genotyping

4.8.1 Genomic DNA extraction

This method was used to extract genomic DNA from tail biopsies. The tails were usually obtained while weaning the mice at PD21 and after perfusion for confirmation. Approximately 5 mm of tail was cut and placed in screw capped tail tubes. The tail biopsy was kept at -20°C until lysis. Before genotyping the tail was incubated overnight at 55°C in 200 µl of 1:100 Proteinase K (20 mg/ml) in digestion buffer. The next day Proteinase K was deactivated at 85°C for 45 min. The tail lysate was stored at 4°C until genotyping.

4.8.2 Genotyping protocols

For this thesis it was of great importance to determine unambiguously the genotype of the mice used. Especially for the complex breeding described in Chapter 7, reliable and accurate genotyping was essential. To achieve a high level of certainty, specific primers for each gene-targeted strain and crosses were used to amplify specific DNA sequences of known length using PCR. The table below details the primer pairs used and the PCR program chosen for each strain (Table 4.3). For most strains a primer pair for the wild type (WT) allele and the mutated (MUT) allele was tested. This was not possible for transgene (TG) strains since the locus in the genome is unknown. For each genotyping positive (B6), negative (water) were tested as well.

Table 4.3 List of primers for genotyping

Mutant name	Oligo wildtype	WT band size	Oligo MUT	MUT band size	PCR
M71-IRES-tauGFP	1121B/A114A	309 bp	819/ A114A	~250 bp	PCR 1

For all genotyping reactions a standard reaction mix was used. For each reaction 0.40 ml of each primer at 20 μ M concentration was used. Buffer, dNTPs and Taq were provided by Takara Bio Inc.

Table 4.4 Reaction mix

	μ l
H ₂ O	18.08
10 x Puffer	2.50
dNTP	2.00
Each primer	0.40
Taq	0.12
Template	1.50
Total	25.00

For genotyping two protocols for PCR were used, internally called PCR 1 and PCR 7. Otherwise the PCR did not differ from the method described in 4.1.1.

Table 4.5 PCR protocols for genotyping

Steps	PCR1	Cycles (35x)	PCR 7	Cycles (40x)
Initial denaturation	95°C	5 min	94°C	5 min
DNA denaturation	95°C	1 min	94°C	45 sec
	60°C	1 min	58°C	30 sec
DNA polymerization	72°C	2 min	72°C	1 min
Final polymerization	72°C	10 min	72°C	10 min
Holding	4°C		4°C	

After PCR amplification the DNA fragments were stained with loading dye and loaded on a 1,5% agarose in TBE gel and the NEB standard was added. The gel was run at 120V in TBE buffer for approximately 30 min. Gel pictures were taken with PeqLab Geldoc.

4.9 Cell counting

Every fluorescent cell body profile with full nucleus in each section of PD21 or younger mice was counted using a Zeiss confocal microscope LSM 510. Each section was counted manually, by direct inspection with the microscope. Sampling methods (Geuna, 2000; Guillery, 2002; Schmitz and Hof, 2005) were not used due to the multitude of distinct spatial expression patterns attributed to zones for OR genes. The sparse and possibly non-homogeneous distribution of OSNs that express a given OR gene make most techniques not practical. Due to the inherently strong tissue shrinkage in cryosections combined with the sparse distribution of labeled cells an optical dissector correction for the z-axis was not used (Benes and Lange, 2001). Instead an empirical strategy was chosen. Counting of up to ~50,000 cells in a mouse is still practical. To get a closer approximation to the real cell numbers the Abercrombie correction (Abercrombie, 1948) was applied to the cell counts. For the correction the average nucleus diameter of 10 cells for each of the 11 core strains for Chapter 6 was measured (Figure 4.4). Subsequently for each strain the correction factor was calculated (section thickness of 12 µm) using the formula (Table 4.6):

$$cell\ number = cell\ count \times \frac{Section\ thickness}{nucleus\ diameter + section\ thickness} (correction\ factor).$$

Table 4.6 Nucleus diameter and correction factor

Strain name	Abbreviation	Nuclear diameter (μm)	Standard deviation ($\pm\mu\text{m}$)	Correction
P3-IRES-tauGFP	P3	4.51	0.80	0.73
M71-IRES-tauGFP	M71	4.26	1.05	0.74
mOR37C-IRES-tauGFP	mOR37C	4.39	0.62	0.73
S50-IRES-tauGFP	S50	4.40	0.91	0.73
MOR23-IRES-tauGFP	MOR23	4.00	0.39	0.75
M72-IRES-tauGFP	M72	4.47	0.74	0.73
M50-IRES-GFP-IRES-taulacZ	M50	4.49	0.79	0.73
ml7-IRES-tauGFP	ml7	4.53	0.65	0.73
P2-IRES-tauGFP	P2	4.53	0.60	0.73
SR1-IRES-tauGFP	SR1	4.49	0.72	0.73
MOR256-17-IRES-tauGFP	MOR256-17	4.59	0.58	0.72
β 2AR \rightarrow M71-IRES-tauGFP		4.26	1.05	0.74
RFP \rightarrow M71iM71iGFP		4.26	1.05	0.74
M71-IRES-tauYFP		4.26	1.05	0.74
M71-IRES-tauRFP2		4.26	1.05	0.74

A priori knowledge or assumptions of OSN distribution in the MOE are not needed, hence this strategy enables analysis and comparison of a relatively large number of strains.

For overview images of the MOE, a Leica Aperio Scanscope FL was used. For mice older than PD21, cells in every fifth coronal section were counted. For statistical analyses and graphs, Graphpad Prism 5 was used.

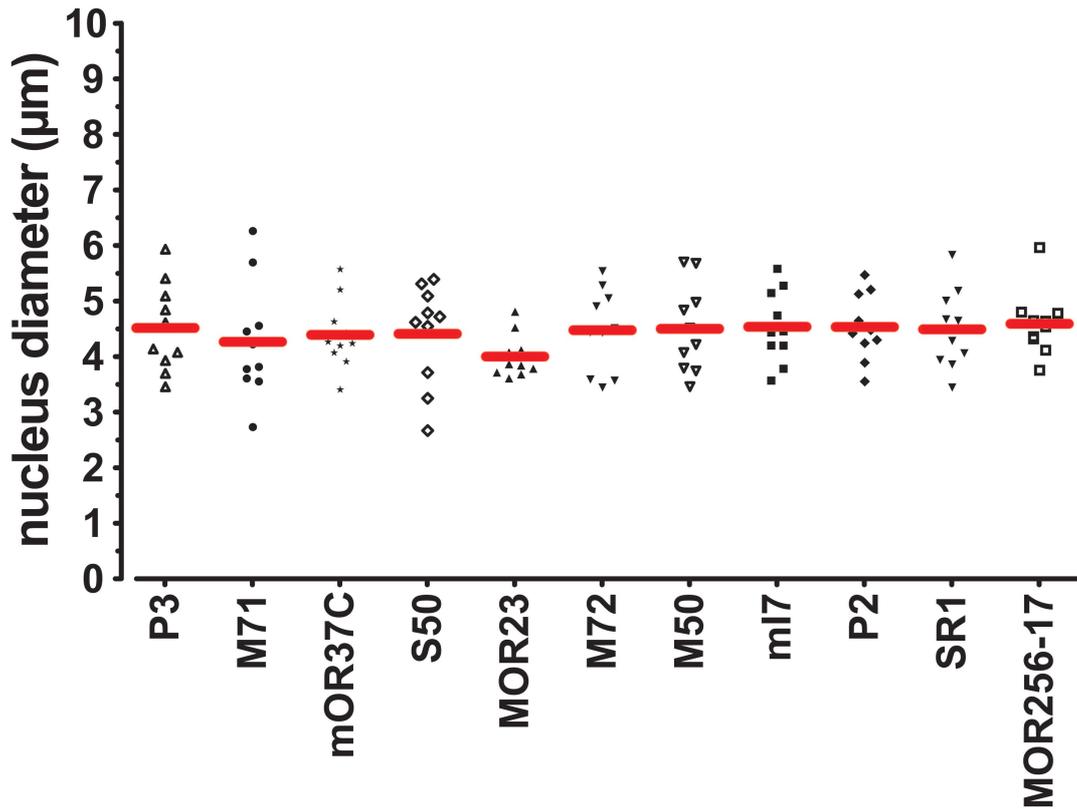

Figure 4.4 Average nucleus diameter

This figure shows the average nucleus diameter measured for 11 gene-targeted strains. Each symbol represents a single OSN measured. For each strain, 10 different OSNs were measured. There is no statistical significant difference between the diameters (One-way Annova, $F=0.52$, $P=0.87$).

4.10 Glomerular reconstruction

The same series of coronal sections used for estimating the OSN numbers were also used to determine the total glomerular volume (TGV) of fluorescent glomeruli in mice at PD21. Images of glomerular sections were taken with the LSM 510. Glomerular reconstruction and fluorescent pixel density measurements in glomeruli were performed using Microsoft Excel, Fiji V1.48u and Matlab V7.12. For statistical analyses and graphs, Graphpad Prism 5 was used.

Glomeruli are distributed on average over five physical sections but can span more than ten physical sections. Glomeruli were not always of elliptical shape so a simple estimation for glomerular volume was not feasible (Schaefer et al., 2001).

First, glomeruli were reconstructed by taking z-stack images with the LSM 510 in 1 μm intervals through all physical sections that contained labeled axons within the glomerular layer, similar to other methods reported (Cummings and Belluscio, 2010). In each optical section of the z-stack that contained a sharp and defined glomerular profile (Figure 4.5), the surface area of the glomerulus was measured. These areas were summed and multiplied with optical section thickness (1 μm) to get a close approximation of the glomerular volume.

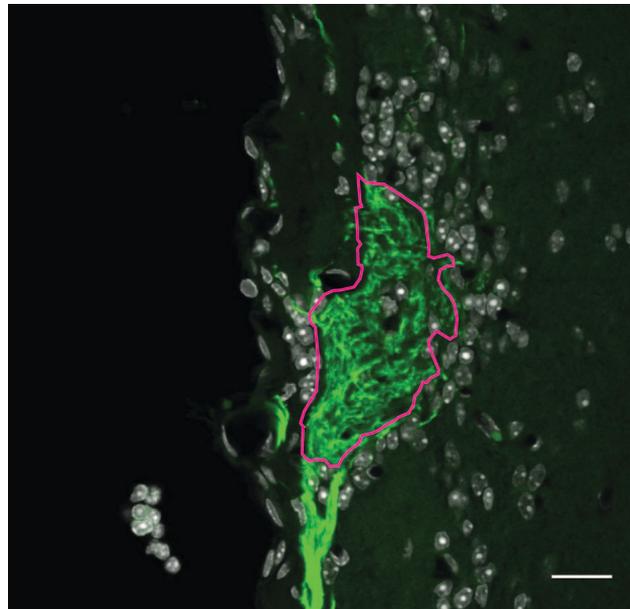

Figure 4.5 Measuring area in optical sections

Confocal image of an M71-IRES-tauGFP glomerulus. Green, intrinsic fluorescence, white: DAPI. Scale bar: 20 μm . The area framed in magenta is measured as the cross sectional area of the glomerulus in this section. Image taken with a 40x lens.

To reduce the labor of volume reconstruction, this thesis shows that a close approximation can be achieved by analyzing a single optical section per physical section. These optical section profiles from the middle of the physical section are summed and multiplied then with a factor of 12 μm (the section thickness). The sum of all glomerular volumes of fluorescently labeled glomeruli per mouse is the TGV. This measure decreases the variance and corrects for differences in the numbers of glomeruli.

4.11 Measuring fluorescent pixel density

Fluorescent pixel density of a glomerulus was calculated by using the 40x confocal images of the optical sections used for TGV reconstruction. Images were loaded into a Matlab program. The background fluorescence was defined for each image in labeled regions of the glomerular layer close to the labeled glomeruli, and a threshold was set at mean background pixel intensity of the image plus three times the mean backgrounds standard deviation. The area of fluorescence was measured manually as for the glomerular volume. All pixels above threshold in the glomerular area were measured, and the ratio to the entire glomerular area was calculated as the fluorescent pixel density.

5 Generating a gene-targeting vector for the M71 locus

5.1 Results

Axonal wiring in the mouse olfactory system is a complex endeavor for the nascent OSN axon and still not fully understood. In 2006, Imai and colleagues (Imai et al., 2006) reported that a mutation in the G-protein binding site of the rat I7 OR (rI7) receptor abolishes axon wiring in OSNs expressing this receptor in transgenic mice. Axonal wiring can be recovered by expression of a constitutively active $G_{\alpha s}$ subunit (caGs). Expression of caGs in wild-type rI7 expressing OSNs shifts the glomerular position more posteriorly. The model that has emerged from these results is that the basal level of cyclic adenosine monophosphate (cAMP) plays a crucial role in glomerular positioning along anterior-posterior axis. In the present study I tried to generate gene-targeted strains with a knockin of caGs in M71-expressing OSNs as opposed to the transgenic random integration approach by Imai and colleagues (2006).

Unfortunately, the generation of a new gene-targeting vector needed to knockin caGs in the M71 locus failed despite of two approaches, which are described in the following paragraphs (5.1.1 and 5.1.2).

The process of generating the gene-targeted strains starts with the cloning of the targeting vector. In short, a sequence fragment consisting of the desired mutation is designed to be flanked by ~5,000 bp arms that are homologous to the genome. The completed targeting vector is then linearized and electroporated in E14 embryonic stem cell lines. The correct clone with the mutation is then screened by Southern blot. The positively identified clone is afterwards microinjected in C57BL/6J blastocysts which are then transferred to pseudopregnant CD1 mothers. Among the resulting mice are chimeras, and male chimeras are bred with C57BL/6J females to generate F1 offspring. Germline transmission is often confirmed by coat color identification, followed by Southern blot analysis of the tail biopsies.

5.1.1 First strategy

The cloning steps of the targeting vector for the M71 locus is described in Chapter 4.1.8. The cloning steps were based on modifying the existing targeting cassettes for the M71 locus available in the lab. The task was to insert a new cassette “IRES-caGs” into an existing targeting vector, M71-IRES-tauGFP thereby creating a tricistronic vector, M71-IRES-caGs-IRES-tauGFP. Successful cloning steps were achieved resulting in the plasmid pOB08 (Figure 5.1A). Test restriction digest with three restriction endonuclease pairs (EcoRI/NcoI, NcoI/PacI & EcoRI/PacI, Figure 5.1B) showed the correct insertion and direction of the sequence (left example). Subsequently the correct plasmids were sent out to Qiagen for sequencing.

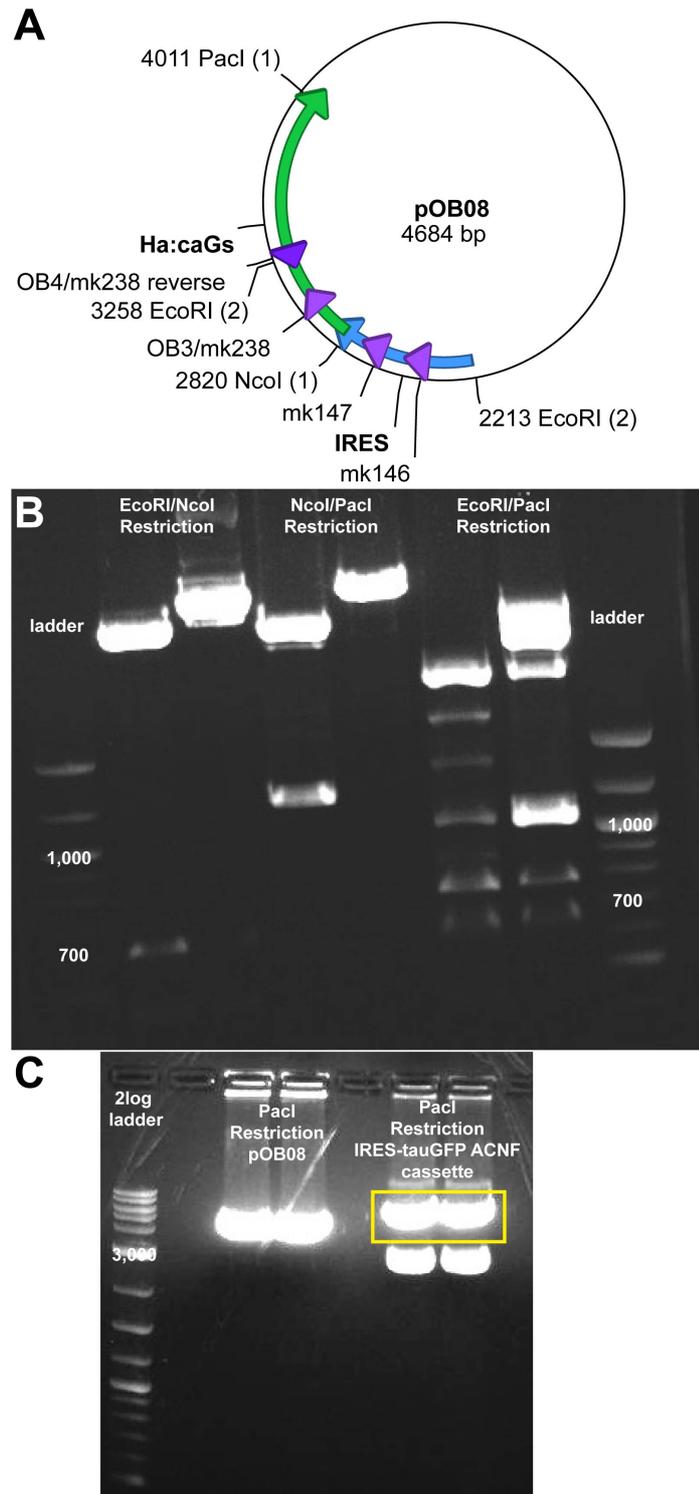

Figure 5.1 Generating gene-targeting vector 1

(A) Vector map of the pOB08 vector. This was the last step (step 2, [Figure 4.1](#)), which gave positive results. Purple arrowheads represent primer binding sites for genotyping and sequencing. The arrow tip shows the direction of primer. Long arrows represent the insert, indicating the direction. Also shown are the restriction sites used in confirmation of targeting and as further insertion sites. (B) Gel electrophoresis of test restriction with three restriction endonuclease pairs (EcoRI/NcoI, NcoI/Pacl, EcoRI/Pacl) for two pOB08 plasmids (left and right lane). Expected bands additional to vector band (2000 - 3000 bp) are: EcoRI/NcoI 486 bp & 473 bp, NcoI/Pacl 1185 bp, EcoRI/Pacl 1050 bp & 757 bp. (C) Gel electrophoresis of PaclI restriction for two clones of pOB08 (left lanes) and two IRES-tauGFP ACNF plasmids. The yellow box highlights the band excised as insert for step 3.

After the confirmation by sequencing the final step involved cloning the IRES-tauGFP-ACNF cassette into pOB08 by PacI ligation (Figure 5.1C). However after several attempts using different clones of the IRES-tauGFP-ACNF plasmid and pOB08 forming the final plasmid pOB09 (Chapter 4.1.8) and despite intense screening and sequencing, a clone with the correct insert, which would have generated the full tricistronic construct, could not be identified. Different competent cell lines were used to facilitate correct plasmid amplification (dH5 α , XL2-Blue Ultracompetent cells, MAX efficiency DH5a).

5.1.2 Second Strategy

Another approach was attempted; using another targeting vector donor available in the lab (IRES-gapCFP-ACNF) the fluorescent protein tauCFP was used as a reporter gene and with an additional linker the M71 targeting vector available in the lab was used (restriction endonuclease targeting site for PacI after M71 sequence). The assembly of the insert for the targeting vector worked and resulted in the plasmid pOB13 (IRES-caGS-IRES-gapCFP-ACNF, Figure 5.2A). Correct assembly was confirmed by PCR and restriction enzyme digest to identify correct clones (Figure 5.2B). However I encountered the same difficulty in the final ligation step to generate the tricistronic vector pOB13 (Figure 5.2C). After several attempts over months the project was finally suspended due to time constraints.

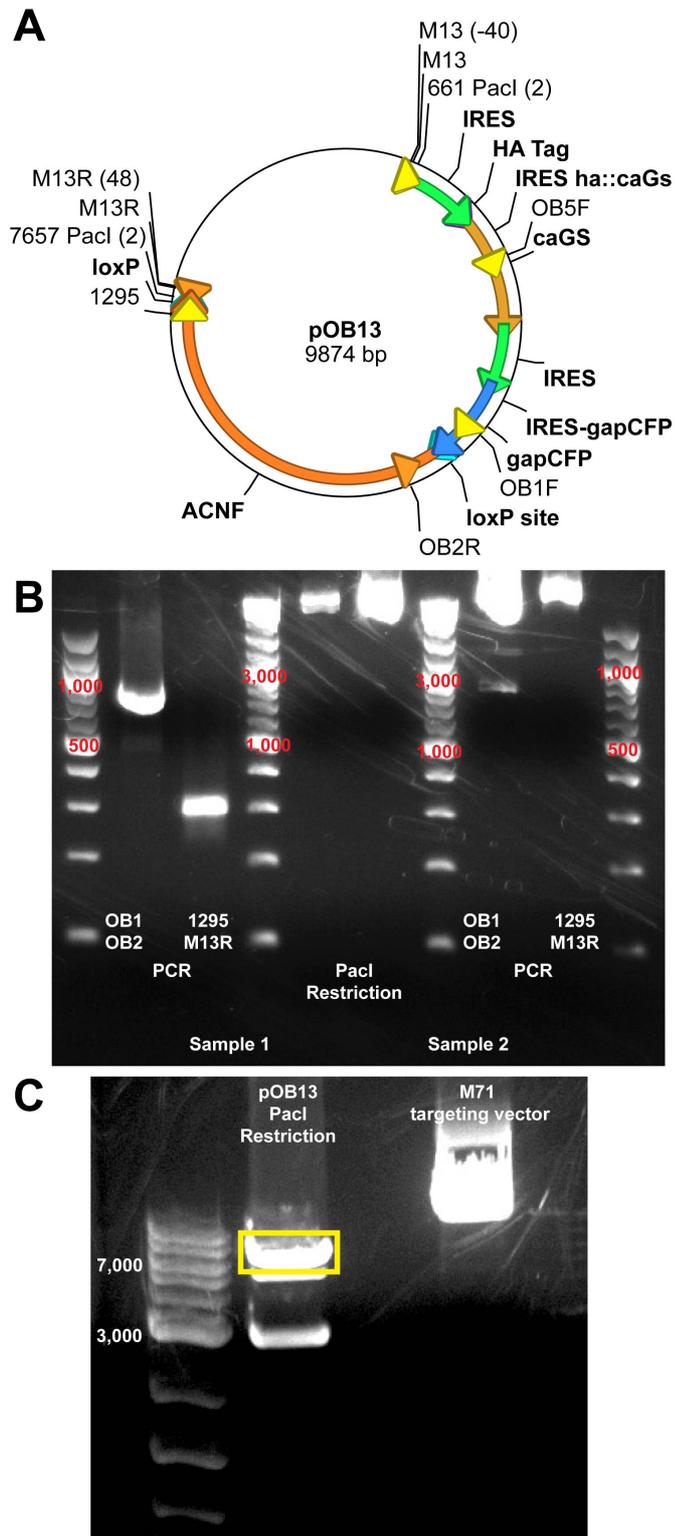

Figure 5.2 Generating gene-targeting vector 2

(A) Vector map of the pOB13 vector. This was the last step, which gave positive results. Yellow arrowheads represent primer binding sites for genotyping and sequencing. The arrow tip shows the direction of primer. Long arrows represent the insert, indicating the direction. Also shown are the restriction sites used in confirmation of targeting and as further insertion sites. (B) Gel electrophoresis for PCR for primer pairs OB1/OB2 (700 bp) and 1295/M13R (280 bp) and test for linearization with Pacl restriction for two samples of pOB13 targeting vector. Sample two is negative for correct inserts. (C) Gel electrophoresis of Pacl restriction of pOB13 and M71 targeting vector. Yellow box indicates 7000 bp band excised for insertion in M71 targeting vector after gel extraction.

5.2 Discussion

Unfortunately both strategies to generate a gene-targeting vector that expresses caGs and a fluorescent reporter gene from the M71 locus failed. There are several explanations why no correct and functional plasmid was obtained. One possibility is that the double IRES sites in the construct are toxic for the competent cells, or just very hard to correctly amplify due to the long GC rich sequence in IRES. It might be that the two IRES sequences interact because of the highly repetitive sequence homology and a recombination event occurs. In several sequencing results of the plasmids the sequence of the inserts seemed to be incorrect or not in the right orientation. Another problem might be the size of the vectors, which might influence the amplification of the plasmid.

I initiated this project to test the hypothesis of a prevailing model that cAMP determines the positional axis of glomeruli. Although the final cloning steps failed, I have gained a lot of insights and experience in targeting vector construction.

6 Quantitative analysis of gene-targeted strains

6.1 Results

The chemosensory system in mouse relies on the expression of ~1,200 OR genes across millions of OSNs for specificity. These millions of OSNs in the MOE project their axons to the OB and form ~3,600 glomeruli. In this chapter 17 gene-targeted strains are reported of the OR-IRES-marker design coexpressing a fluorescent protein or τ -taulacZ.

Representing a 1% sample of the OR gene repertoire, 11 strains were selected for detailed analysis. All serial coronal sections were evaluated quantitatively using confocal microscopy - a total of 685,673 cells in 56 mice at postnatal day 21 were counted. A strain-specific Abercrombie correction to these OSN counts was applied, in order to obtain a closer approximate of the true OSN numbers. In the same series of coronal sections, the total volume of the glomeruli (TGV) formed by coalescence of the fluorescent axons was measured, finding a strong linear correlation between OSN number and TGV. This leads to the conclusion that the glomerular volume is a possible estimate for cell numbers.

Most of these data have been published in Bressel et al. (2015).

6.1.1 Cell counts

The OSN numbers in the core set of 11 strains representing the 11 gene-targeted OR genes after Abercrombie correction at PD21 are, from low to high: P3 ($2,236 \pm 247$ cells), M71 ($2,419 \pm 484$), mOR37C ($2,660 \pm 175$), S50 ($3,289 \pm 503$), MOR23 ($4,446 \pm 327$), M72 ($5,265 \pm 906$), M50 ($6,716 \pm 648$), ml7 ($9,892 \pm 1,852$), P2 ($13,975 \pm 1,982$), SR1 ($23,846 \pm 1,706$), and MOR256-17 ($37,023 \pm 6,318$) (Figure 6.1). The average OSN number has thus a range of 17-fold across these 11 OR-tagged strains. Importantly, the spread within a given OR-tagged strain is fairly small (see also below, coefficient of variation).

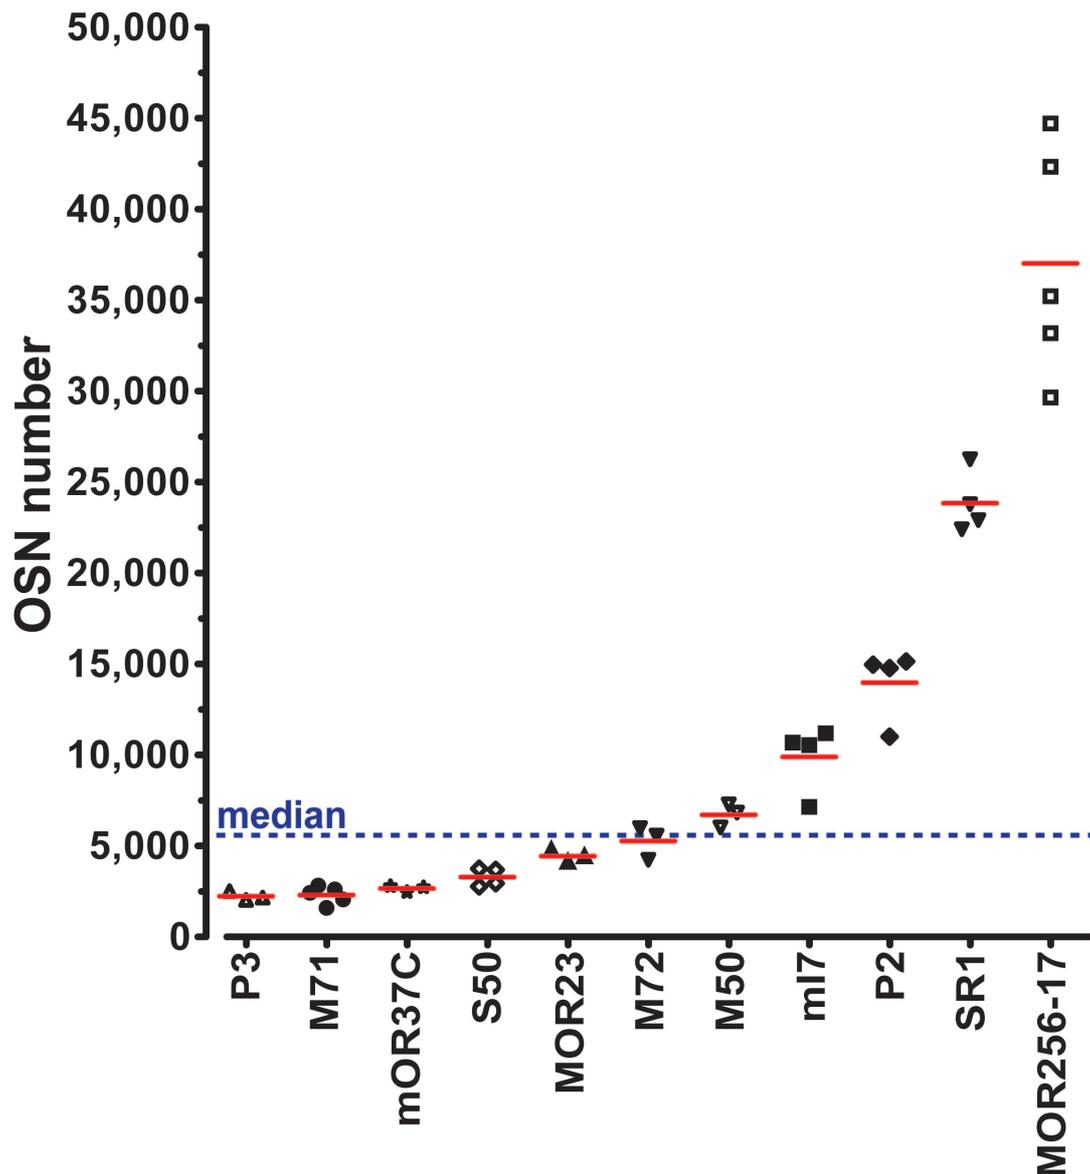

Figure 6.1 Numbers of fluorescent cells in OR-IRES-tauGFP strains

Average OSN number of the core set of 11 gene-targeted strains at PD21. A symbol represents a single mouse. The blue line indicates the median of 5,983.

The numbers of fluorescent cells in six other strains with mutations in the *M71* gene are: $\beta 2AR \rightarrow M71\text{-IRES-tauGFP}$ (460 ± 131), $\beta 2AR \rightarrow M71\text{-IRES-taulacZ}$ (1475 ± 334), $RFP \rightarrow M71iM71iGFP$ (650 ± 77), $M71\text{-IRES-tauYFP}$ ($1,558 \pm 156$), $M71\text{-IRES-tauRFP2}$ ($1,893 \pm 14$) (Figure 6.2) and $M71\text{-IRES-taulacZ}$ (4610 ± 579). There is no significant difference (t-test, $p = 0.21$) in OSN numbers between $M71\text{-IRES-tauGFP}$ and $M71\text{-IRES-tauRFP2}$ (red fluorescent protein), indicating a similar probability of OR gene choice and sensitivity of detection of intrinsic fluorescence. The OSN number in $M71\text{-IRES-tauYFP}$ mice (yellow fluorescent protein) is lower than in $M71\text{-IRES-}$

tauGFP mice (t-test, $p = 0.022$) and M71-IRES-tauRFP2 mice (t-test, $p = 0.015$), reflecting a possible difference in probability of OR gene choice and/or in sensitivity of detection of intrinsic fluorescence. OSN number is significantly higher in the strain expressing taulacZ as a reporter gene (t-test, $p = 0.0003$). OSN numbers are decreased in mutations in which the *M71* coding region is replaced by that of the β 2-adrenergic receptor (β 2AR→M71-IRES-tauGFP) (t-test, $p < 0.0001$) and (β 2AR→M71-IRES-taulacZ) (t-test, $p = 0.02$) or in which M71 translation is decreased by an *IRES*-mediated knockdown (hypomorph, RFP→M71iM71iGFP) (t-test, $p = 0.0007$).

There are $2,067 \pm 441$ OSNs in M71-IRES-tauGFP mice ($n=3$) at PD70, which is not significantly different (t-test, $p = 0.52$) from PD21. For the hypomorph there is no difference either between PD21 and three mice at PD70 (660 ± 248 cells) (t-test, $p = 0.93$).

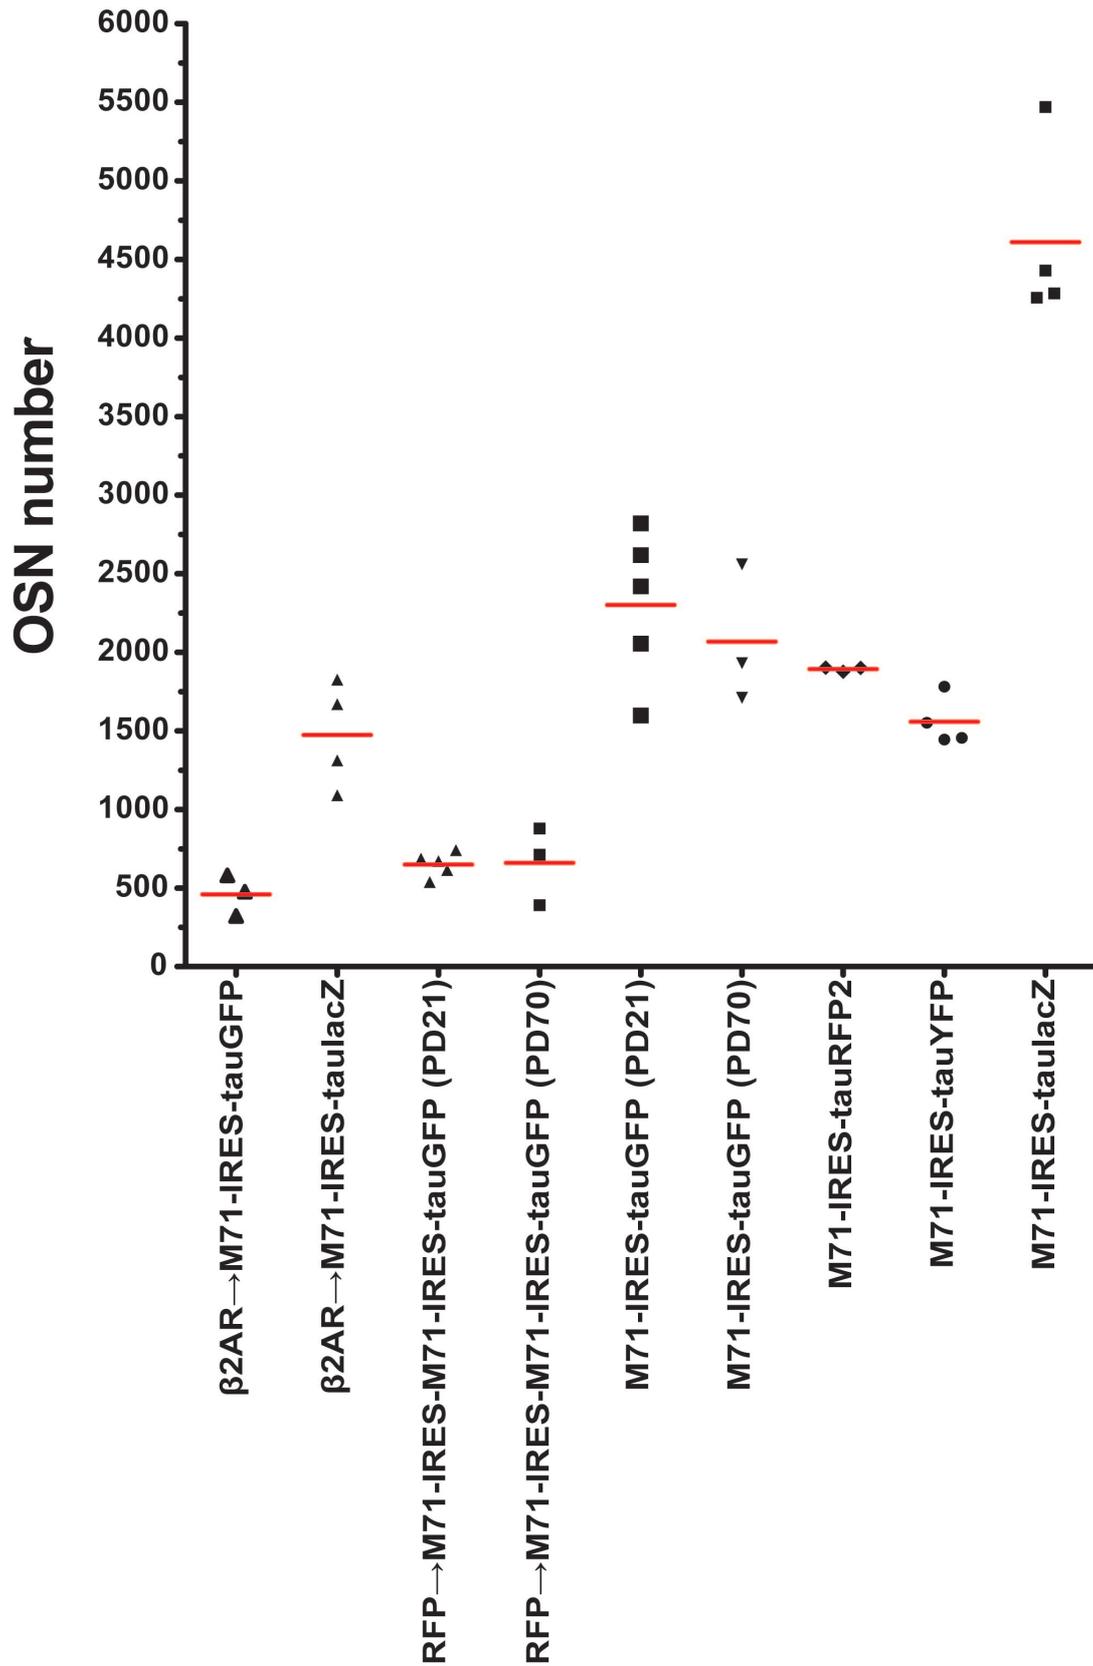

Figure 6.2 Numbers of fluorescent cells in M71-expressing strains
 Average OSN number for strains with gene-targeted mutations in the *M71* locus at PD21 or PD70. The five mice of M71-IRES-tauGFP at PD21 in Figure 6.2 are the same as in Figure 6.1.

6.1.2 Sampling error

Partial cell counts from sampling are typically reported in the literature, because of the time and effort required to make full cell counts. The availability of full cell counts provides a unique opportunity to determine exactly the error that would have been introduced by interleaved sampling. Data sets of n size were generated for the full cell counts, corresponding to n th section sampling for the core set of 11 strains (Figure 6.3); for example, there would be 10 data sets consisting of cell counts in each 10th section. For each data set, the cell counts were summed and multiplied by the sampling interval; in this example, multiplied with 10.

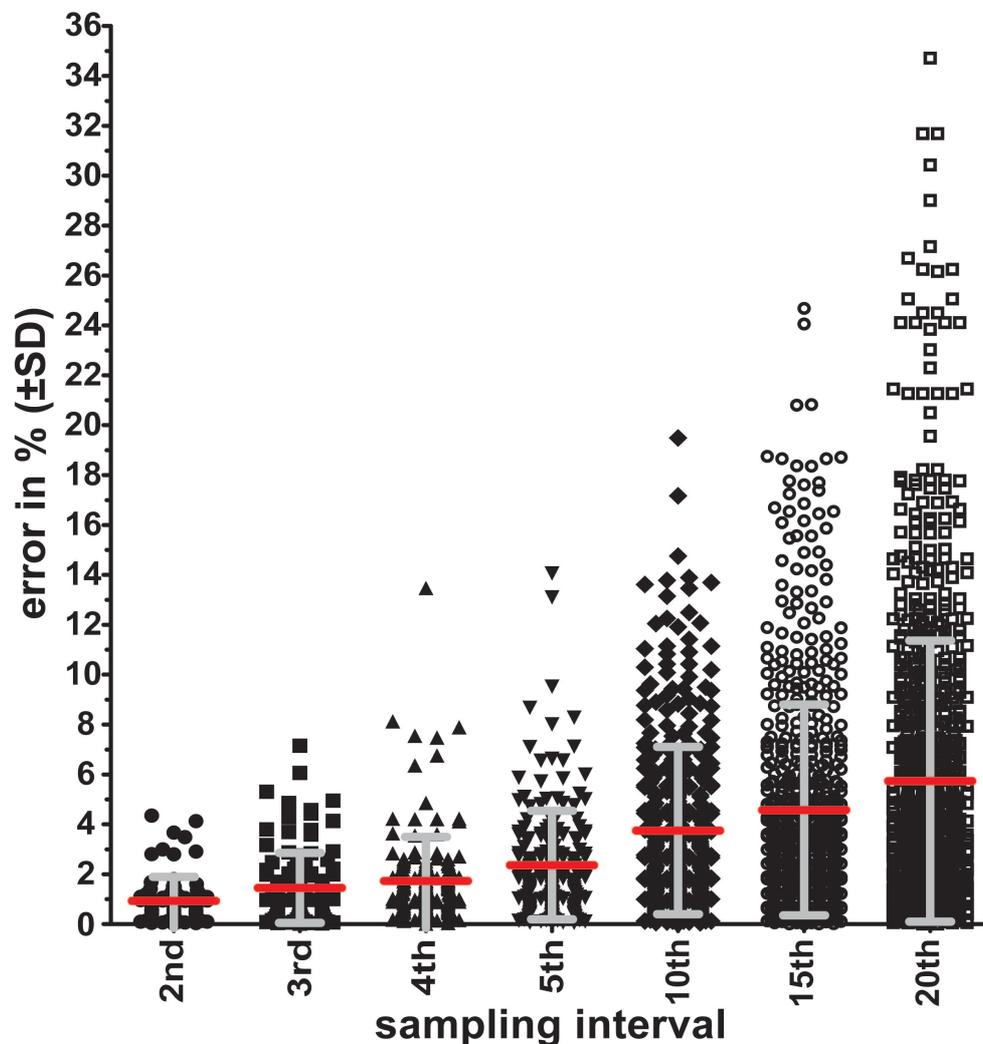

Figure 6.3 Effect of sampling interval

Average percentage of difference (error) in interleaved sampling compared to the "count every cell" approach (\pm SD). Errors for all tauGFP strains for each sampling interval were pooled to calculate the averages. A symbol represents a single virtual sampling set.

The error produced by interleaved sampling can then be calculated by comparing the summed counts of a virtual data set to the original full cell count. The error and standard deviation increase rapidly with decreased sampling interval, and are higher for strains with low OSN numbers such as P3-IRES-tauGFP than for strains with high OSN numbers such as MOR256-17-IRES-tauGFP (Figure 6.4).

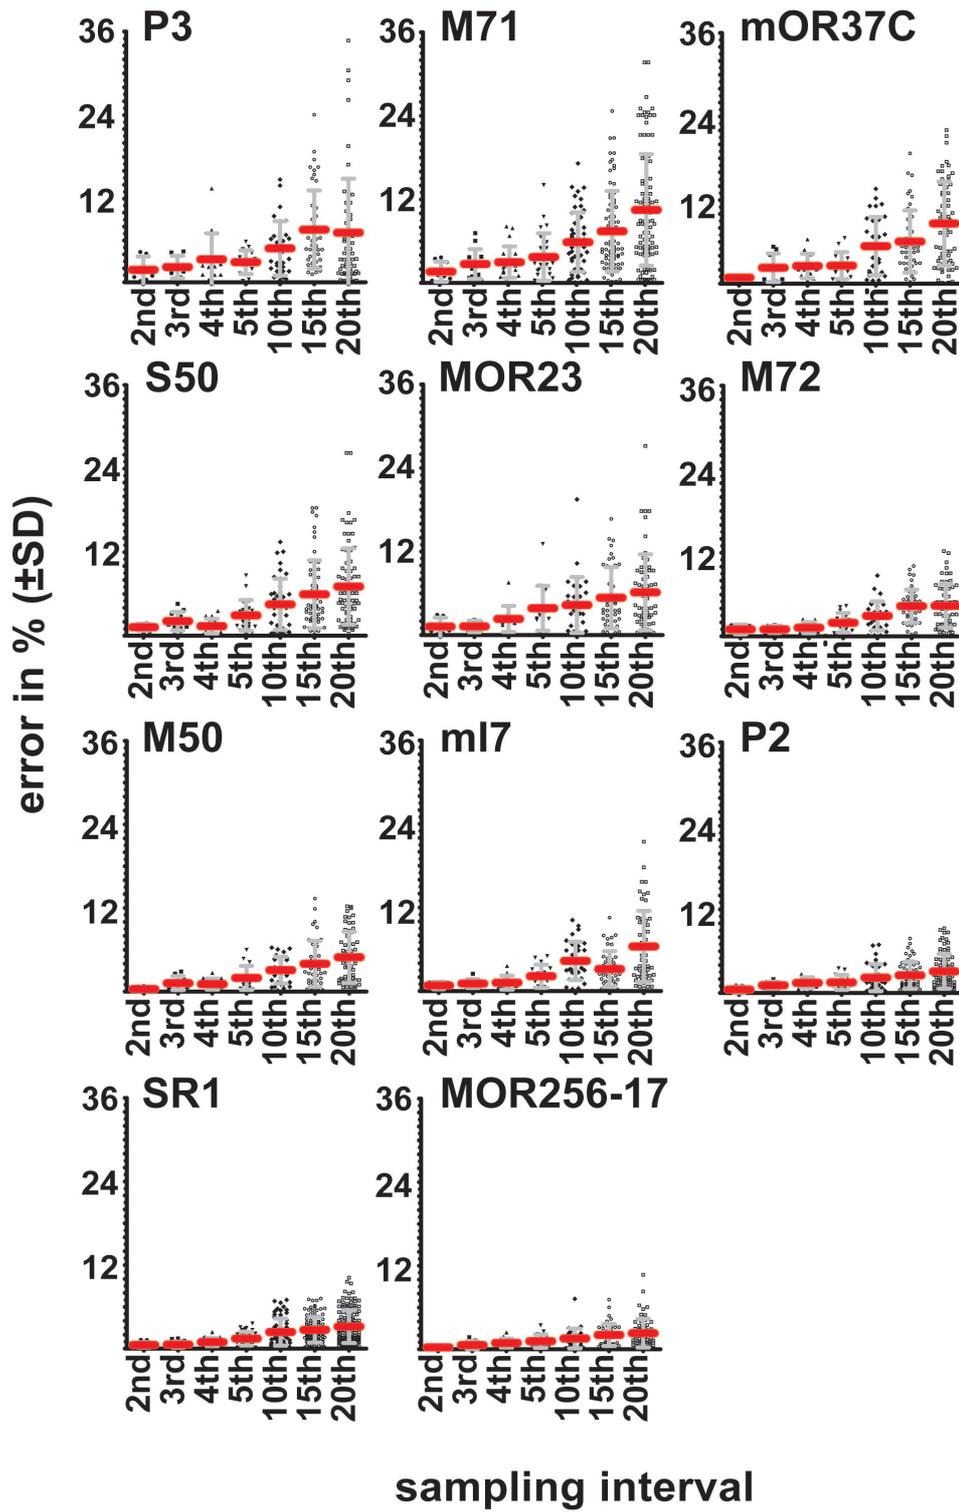

Figure 6.4 Sampling error per strain

Error of cell counts by sampling interval for GFP-expressing strains sorted by average OSN number, from P3, low, to MOR256-17, high. A symbol represents a single virtual sampling set.

6.1.3 Coefficient of Variation

The coefficient of variation (CV) is the ratio of standard deviation and average. Among the core set of 11 strains, the CV for the OSN number within a strain ranges over a factor of 3.2-fold, from 0.066 (mOR37C-IRES-tauGFP) to 0.21 (M71-IRES-tauGFP), but there is no correlation with average OSN number (Figure 6.5): MOR23-IRES-tauGFP has a similarly low CV (0.074) as SR1-IRES-tauGFP (0.072), but the number of OSNs is 5.5-fold lower. Conversely, M72-IRES-tauGFP has a CV (0.172) similar to that of MOR256-IRES-tauGFP (0.171), but the number of OSNs is 7-fold lower. Thus, the probability of OR gene choice appears to be more constant for certain OR genes than for others. From a practical experimental viewpoint, FP-tagged strains with a higher stability in OSN population size (a lower CV) such as MOR23-IRES-tauGFP are easier to study quantitatively.

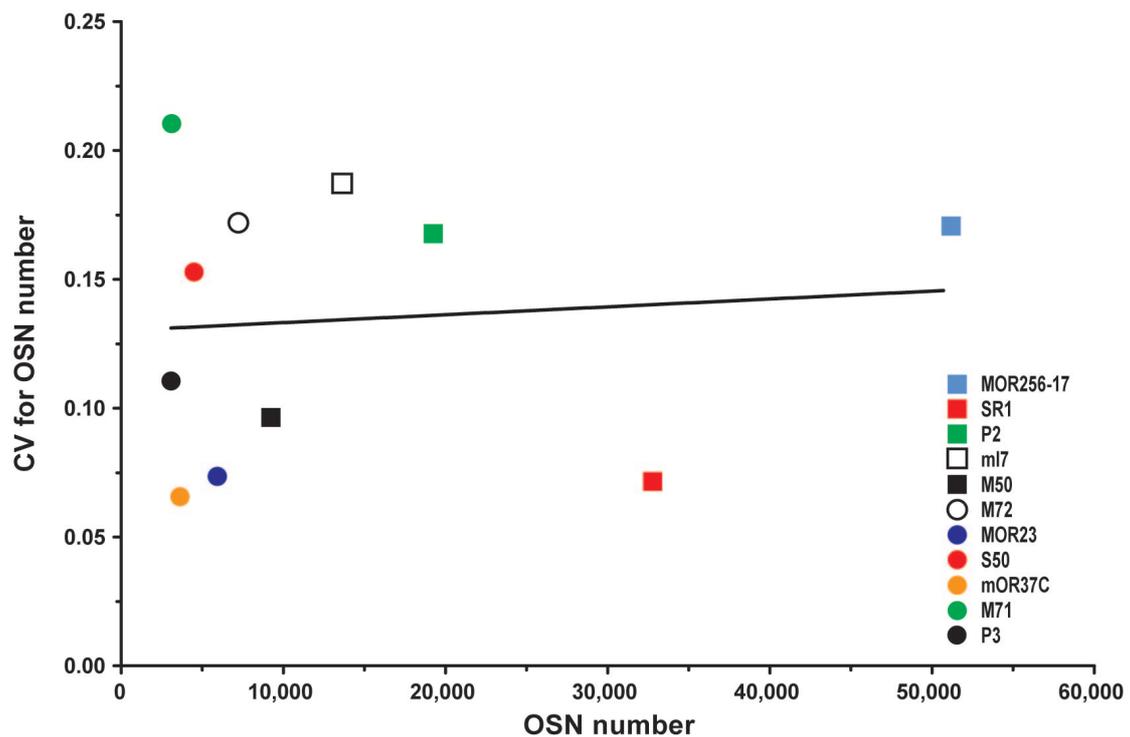

Figure 6.5 Coefficient of variation.

Coefficient of variation (CV) for average OSN number of the 11 tauGFP strains shows that there is no correlation between average OSN number and CV. The line is best modeled by $y = 3.1 \cdot 10^{-7}x + 0.13$ ($r^2 = 0.008$, $p = 0.79$).

6.1.4 Cell counts along the anterior-posterior dimensions of the main olfactory epithelium

As described previously, OSNs expressing a given OR gene display a characteristic spatial pattern across the MOE (Ressler et al., 1993; Miyamichi et al., 2005). With the availability of full cell counts per 12 μm section, plotting the counts along the anterior-posterior dimension of the MOE became feasible. Figure 6.6 shows the diversity of these plots, reflecting the multitude of spatial expression patterns.

- M71
- MOR256-17
- MOR23
- ▲ P2
- ▼ SR1
- ◆ mOR37C

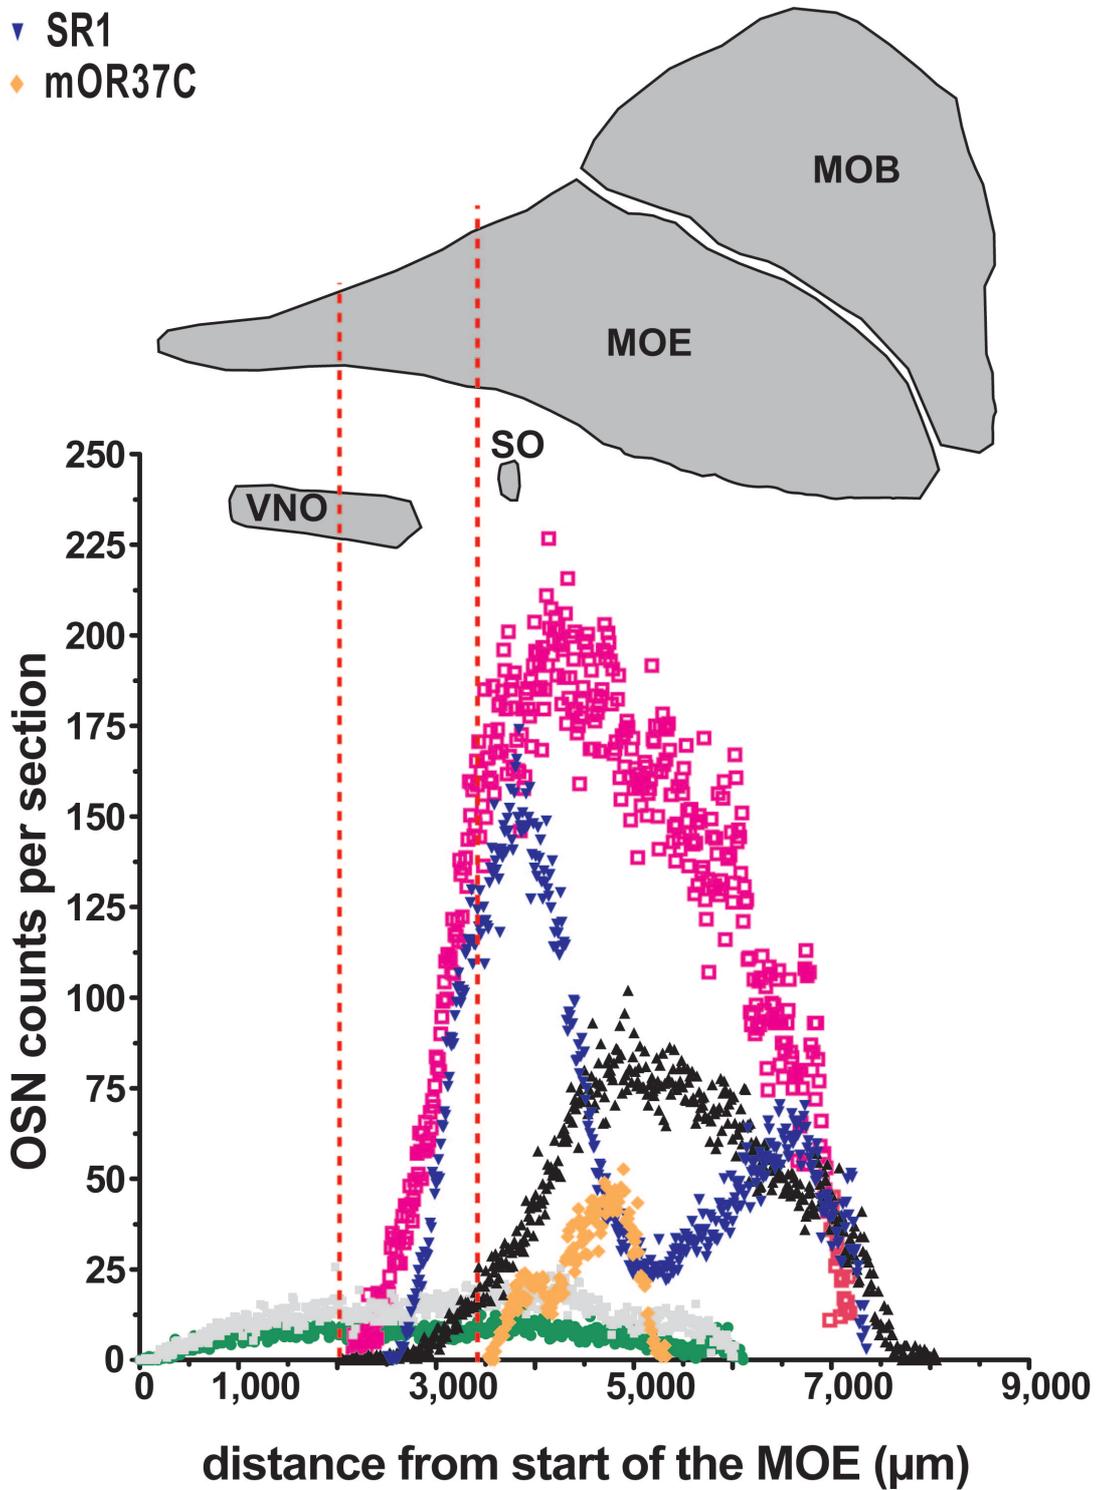

Figure 6.6 OSN counts across the anterior-posterior dimension of the main olfactory epithelium. Average OSN counts per section. The dotted red lines indicate two reference positions in a sagittal view of a mouse head. Strains were chosen for showing the diversity in expression per section. Cells in the septal organ are not included in these counts.

OR genes expressed dorsally such as *M71* and *MOR23* have a relatively even distribution, starting far anteriorly. The relatively even distribution of *M71* is maintained in mutations in which the *M71* coding region is replaced by that of the β 2-adrenergic receptor (β 2AR \rightarrow M71-IRES-tauGFP) or in which *M71* translation is decreased by an *IRES*-mediated knockdown (RFP \rightarrow M71iM71iGFP) (Figure 6.7).

- M71-IRES-tauGFP

- M71-IRES-tauRFP2
- M71-IRES-tauYFP

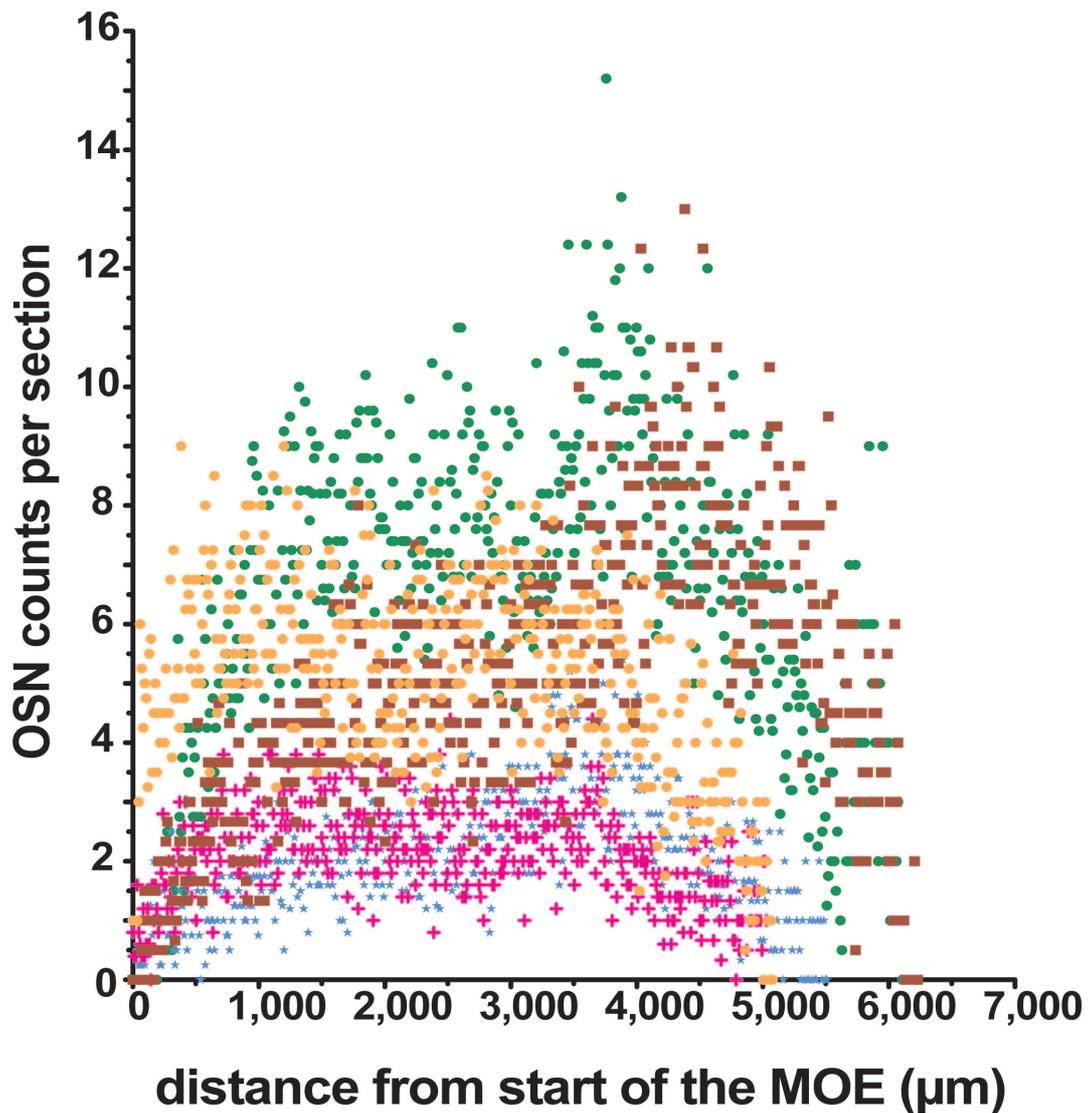

Figure 6.7 Average OSN counts along AP dimensions for strain expressing M71
 Average OSN counts per section for strains with mutations in the *M71* gene along the anterior-posterior dimension showing a similar expression pattern even though the OSN numbers vary.

In contrast OR genes show a single peak (*MOR256-17*) or two peaks (*SR1*) along the anterior-posterior dimension (Figure 6.8). These peaks compromise the accuracy of comparing partial cell counts among individual mice, due to the lack of fiduciary points.

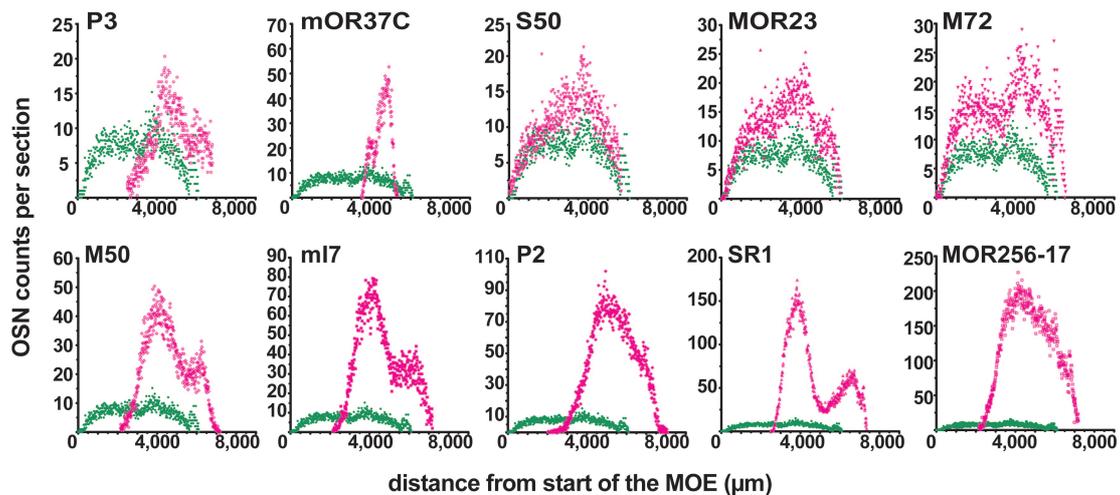

Figure 6.8 OSN counts per section for strains compared to M71
 Average OSN counts per section of (tau)GFP-expressing strains (magenta) compared to M71-IRES-tauGFP (green), sorted by average OSN number from P3, low, to MOR256-17, high. The strains display a multitude of spatial expression patterns/zones.

6.1.5 Glomerular volume and cell counts

The same series of coronal sections as for counting OSNs in the MOE was used to study the glomeruli that correspond to a fluorescent protein-tagged OSN population. The area of a glomerulus displaying intrinsic fluorescence can be calculated by confocal imaging in z-stacks, but this procedure for determining glomerular volume is very time-consuming. Therefore the glomerular volume was computed by reconstruction. The sum of the reconstructed volumes of all fluorescently labeled glomeruli in a mouse is the total glomerular volume (TGV).

There is a strong linear correlation between OSN number and TGV among the 56 mice of the core set of 11 gene-targeted strains analyzed at PD21 (Figure 6.9): $r^2=0.97$ at $p \leq 0.0001$ with an intercept of the Y axis at 168,700 μm^3 and a slope of 81.55. The practical implication of this linear correlation is that TGV, which is relatively easy to compute, can be used to estimate accurately OSN number, which is far more time-consuming to determine.

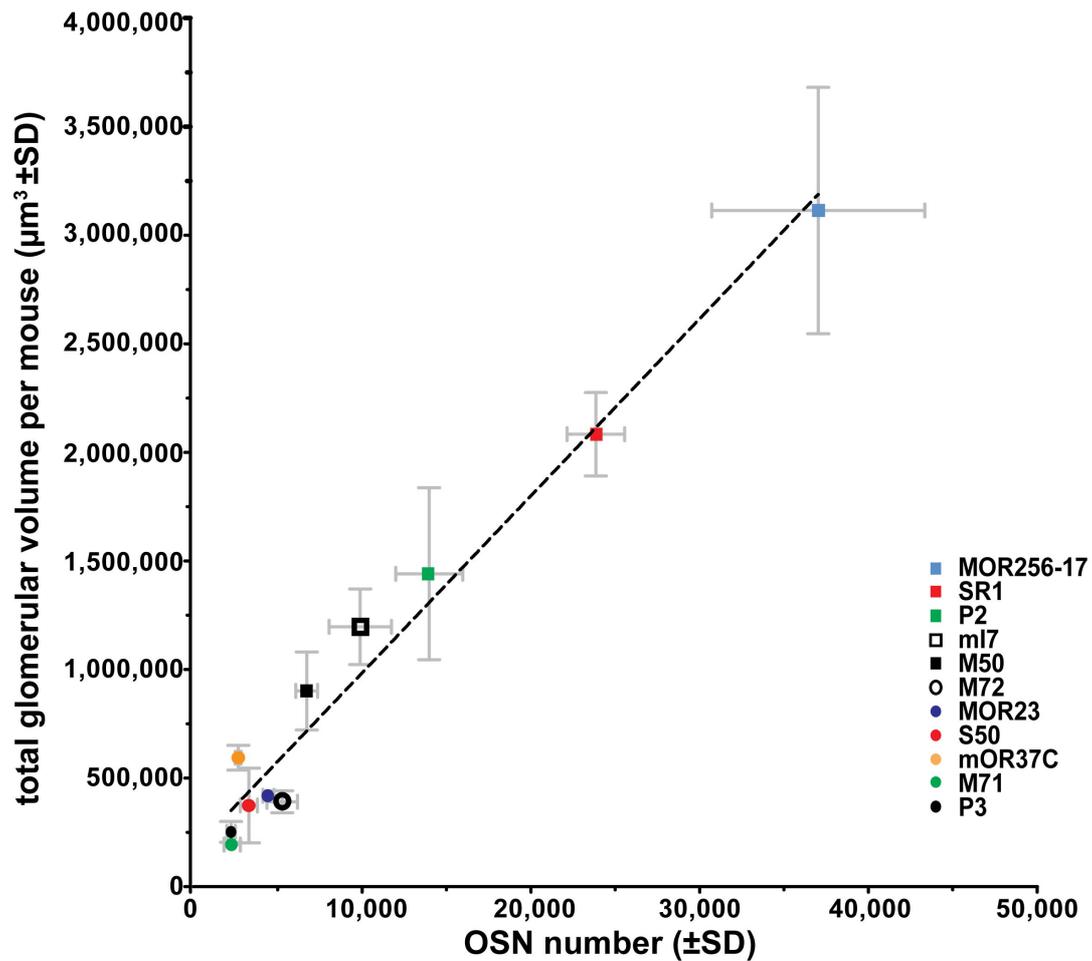

Figure 6.9 Glomerular volume and correlation with OSN numbers for strains coexpressing tauGFP .
 TGV per strain at PD21 correlates strongly and linearly to the OSN number ($r^2 = 0.97$, p -value ≤ 0.0001) in the core set of 11 strains. The curve is best modeled by $y = 81.55x + 168,700$. A symbol represents a single strain.

A strong linear correlation exists as well when considering the strains with different marker genes for M71 (Figure 6.10): $r^2=0.97$ at $p = 0.0018$ with an intercept of the Y axis at $-55,627 \mu\text{m}^3$ and a slope of 121.1. However it was not possible to get a reliable glomerular volume measurement for the two $\beta 2\text{AR} \rightarrow \text{M71}$ strains.

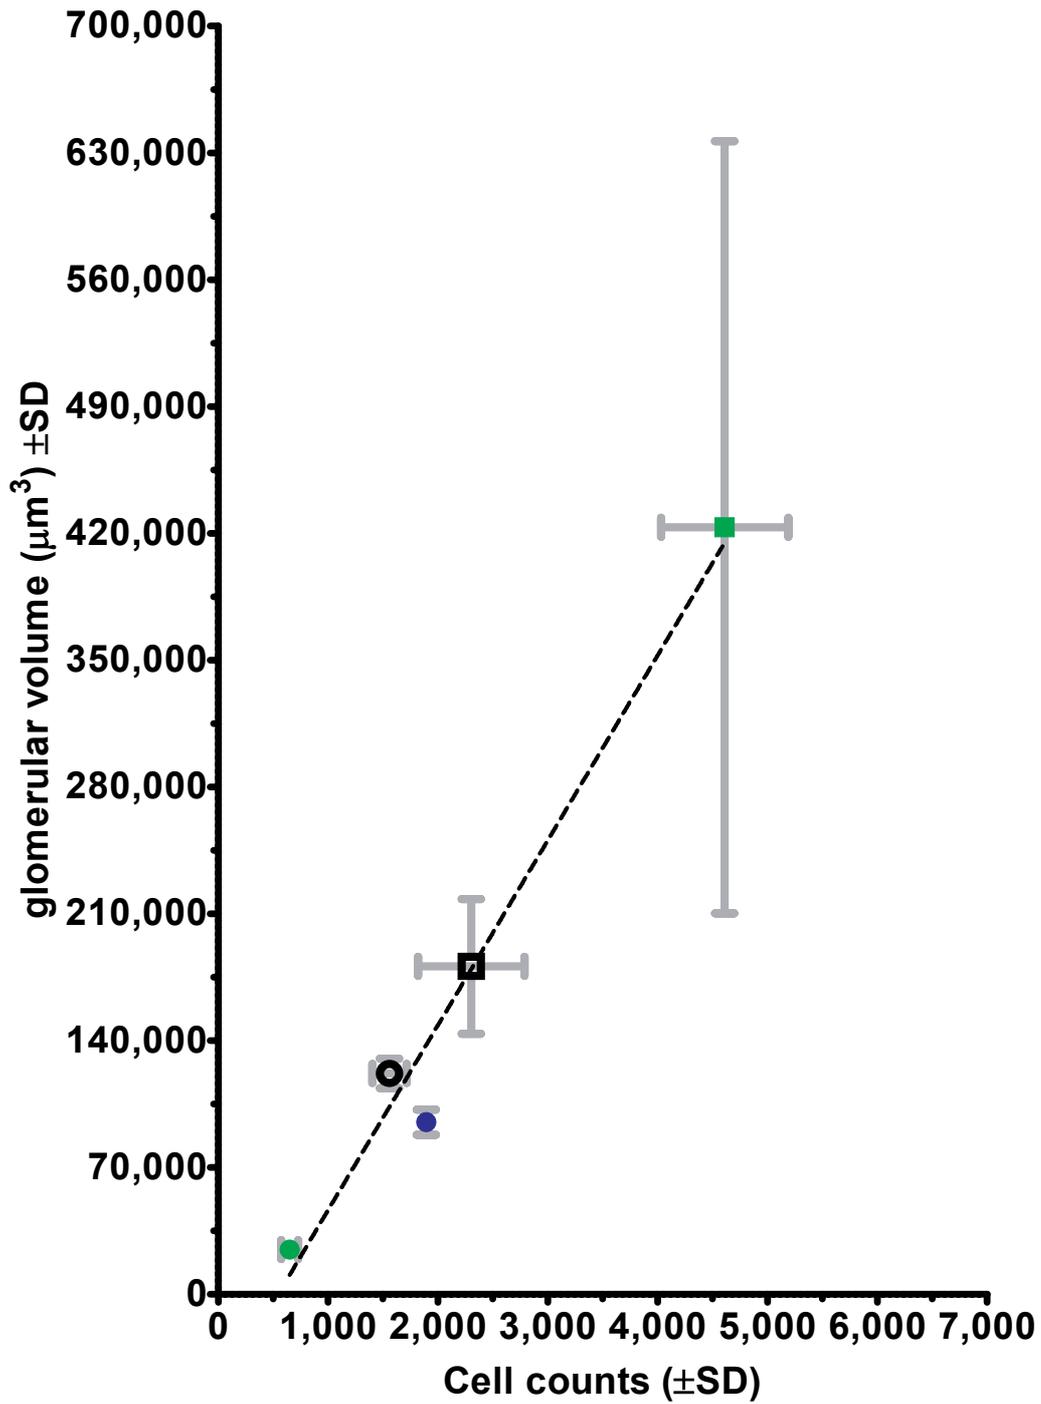

Figure 6.10 Glomerular volume and correlation with OSN numbers for M71-expressing strains
 TGV per M71-expressing strain at PD21 correlates strongly and linearly to the OSN number ($r^2 = 0.97$,
 p-value = 0.0018) in the core set of 11 strains. The curve is best modeled by $y = 121.1x - 55,627$. A
 symbol represents a single strain.

6.1.6 Glomerular density

Finally, fluorescent pixel density of labeled glomeruli was determined in the confocal images used for the reconstruction of glomerular volume. Fluorescent pixel density is an estimate for the density of OSN axon branches and axon terminals within a glomerulus. We find a relatively constant density of ~ 0.80 across the strains; a density of 0.80 means that 80% of the pixels in the glomerulus display fluorescence above background (Figure 6.11).

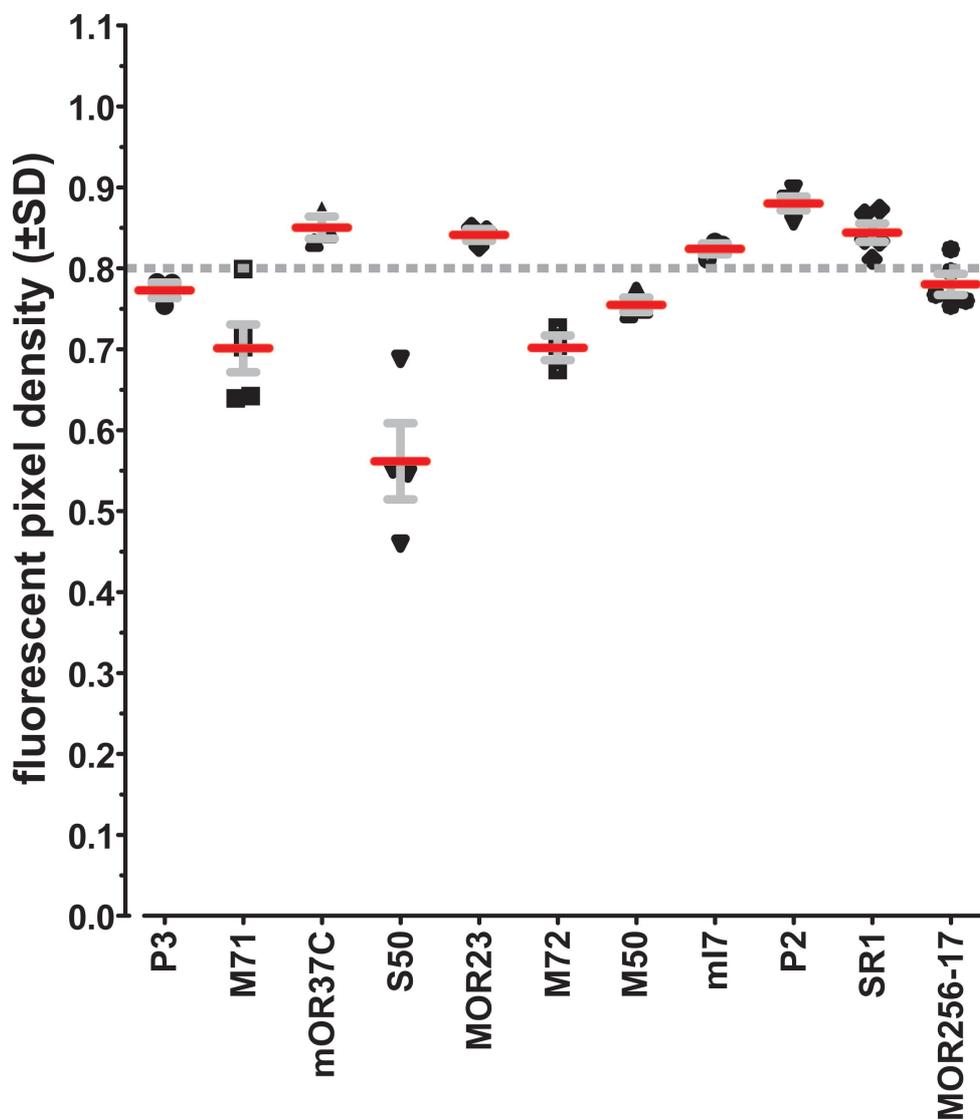

Figure 6.11 Fluorescent pixel density in glomeruli per strains

The ratio of fluorescent pixels to all pixels in the glomerular area is ~ 0.8 in all strains (ANOVA, $F=21.50$, $p < 0.0001$), except for S50-IRES-tauGFP. A symbol represents a single mouse. Strains are sorted by average OSN number from P3, low, to MOR256-17, high.

The S50 glomeruli have a value of 0.56. It turns out that the lateral S50 glomeruli have a value of 0.40 (Figure 6.12). However the medial S50 glomeruli have a normal value of 0.79 (Figure 6.13).

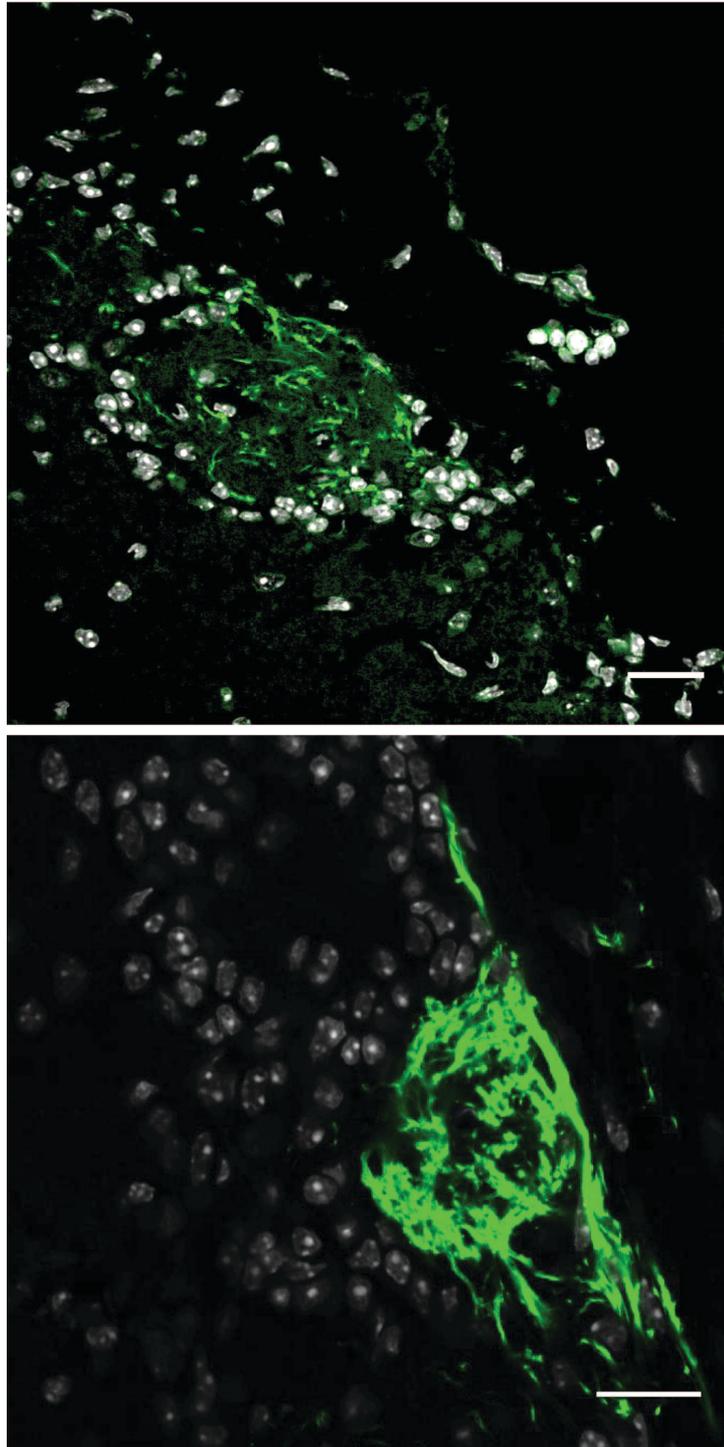

Figure 6.12 Example of a lateral S50-IRES-tauGFP glomerulus

The upper image illustrates the lower fluorescent pixel density in lateral S50 glomeruli, the lower image a medial S50 glomerulus. Green, intrinsic fluorescence; white, DAPI. Scale bar, 20 μ m.

Explanations could be that lateral S50 glomeruli are not yet fully mature by PD21, that they have indeed a lower density of OSN axon branches and terminals, or that they are coinnervated by axons from OSNs expressing another OR.

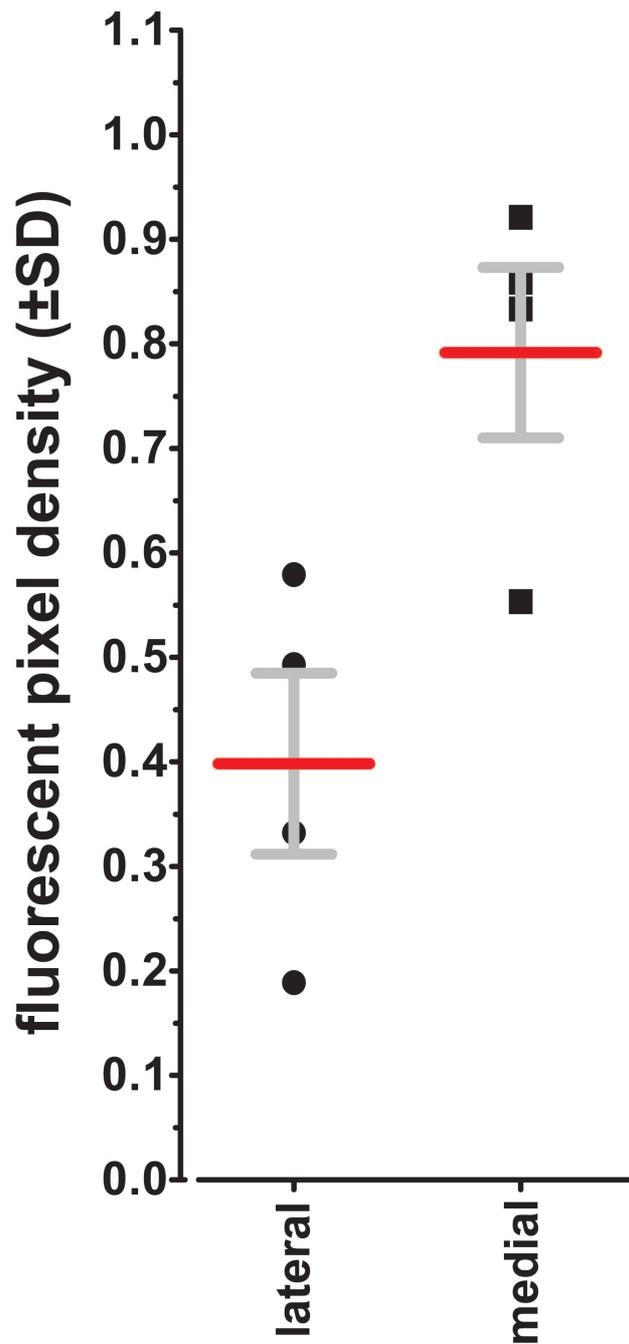

Figure 6.13 Ratios of axonal density for lateral versus medial S50-IRES-tauGFP glomeruli (±SD)
This figure shows that only the lateral glomeruli have a lower fluorescent pixel density. A symbol represents the average of glomeruli in both bulbs of an individual mouse.

6.2 Discussion

The introduction of a genetic strategy based on an IRES and the axonal marker tau β -galactosidase in 1996 (Mombaerts et al., 1996) and the later addition of fluorescent marker proteins (tauGFP and variants tauYFP and tauRFP2) became essential for multiple studies in the olfactory system: they facilitate imaging of glomeruli by confocal microscopy and two-photon microscopy (Potter et al., 2001), they enable physiological studies (Bozza et al., 2002; Grosmaître et al., 2006; Grosmaître et al., 2009; Omura and Mombaerts, 2015), they allow for flow-cytometric cell sorting (Khan et al., 2011) and the manual picking of single cells expressing a given OR gene (Li et al., 2004; Fuss et al., 2010). Therefore this chapter is focused on mice of strains with a gene-targeted mutation in an OR gene that generates a fluorescent protein.

A lingering belief is that each of the ~1,100 OR genes is expressed in a similar number of OSNs. This chapter shows a factor of 17-fold between the smallest OSN population (P3-IRES-tauGFP) and the largest OSN population (MOR256-17-IRES-tauGFP) at PD21, in the 1% sample of the ~1,100 OR genes. Provisionally the median of 5,983 as the OSN number for the average OR gene at PD21 is the prudent estimate. In turn, this number of 5,983 results in an estimate of ~6.6 million OSNs expressing any of the 1,100 OR genes in a mouse at PD21 in this mixed 129 x B6 background. This estimate is lower than the estimate of ~9,400 OSNs expressing on average a given OR gene in the ~10 million mature, OMP-expressing OSNs in 8-week-old C57BL/6J mice (Kawagishi et al., 2014). But the age difference of 3 versus 8 weeks is substantial, and the fraction of OMP-expressing OSNs that does not express an OR gene is not known.

A broad range of NanoString counts for OR mRNAs in wild-type C57BL/6 mice was reported (Khan et al., 2011, 2013): 92% of OR genes have NanoString counts within a 32-fold range. These NanoString counts are not directly translatable into OSN numbers, for several reasons (Khan et al., 2013). The probabilities of OR gene choice appear to differ widely across the OR gene repertoire, and the mechanistic basis of these differences remains to

be clarified. OSN survival and turnover are likely dependent on the odorant composition of the inhaled air which in turn may contribute to the innervation and activity of the OSNs. Therefore Chapter 3.1 contains information about the type of caging, food, and bedding being used. It is conceivable that OSN counts may be different in mice that are housed in other types of caging (such as open cages versus individually ventilated cages) or given other food and bedding.

The empirical strategy generates total cell counts, which appear rarely in the literature presumably due to the amount of effort that is required. A rare example of total cell counts can be found in Royal and Key (1999). Counting cells expressing the OR gene P2 by X-gal histochemistry in P2-IRES-tauLacZ mice but without Abercrombie correction, Royal and Key reported 8,286 labeled cells at PD14.5 and 13,729 at 12 weeks, whereas here $13,975 \pm 1,982$ labeled cells at PD21 in P2-IRES-tauGFP mice are reported.

It appears that the choice of marker proteins has a significant effect on the cell number for the M71 strain. A downregulation of the expression of M71 in the strain RFP→M71iM71iGFP results not only in 68% less expression of the protein in the axon terminus (Zhang et al., 2012) but also in a 73% decrease in OSN number compared to M71-IRES-tauGFP at PD21. The decrease in OSN number in RFP→M71iM71iGFP is also correlated with TGV. The significant higher OSN numbers for the strain M71-IRES-taulacZ compared to M71-IRES-tauGFP could be further verified by performing RNA in situ hybridization of M71 specific probe on C57BL/6J tissue section. However, generation of M71 specific probe proved to be challenging since *M71* and *M72* genes are highly homologous to each other.

From the complete data sets n virtual data sets were generated, as if cells on every n th section had been counted, in n successive data sets, calculating the exact error that is produced by interleaved sampling. This chapter reports that, as expected, the standard deviation increases rapidly with increasing interval, reaching ± 5.63 for every 20th section (average error 5.75%). The information provided about the 11 strains enables now to define *a priori* the acceptable error for studies in which cell counts are compared between experimental conditions.

Counting OSNs expressing a given OR gene or fluorescent protein remains a manual enterprise, no reliable automated methods have been developed thus far. This chapter reports a surrogate for cell counting, computing TGV, which takes far less effort. Reconstruction of these volumes can be done easily by measuring the glomerular area in the middle optical section of physical sections under a confocal microscope, reducing the number of sections analyzed drastically (see Chapter 6.1.2). The very strong linearity of the correlation between OSN number and TGV, over a range of 17-fold, implies that estimates of OSN numbers can be read out from the provided dataset. These findings are consistent with the linear correlation that has been described between partial cell counts in the MOE of M71-IRES-*taulacZ* mice and the average largest cross-sectional area of an M71 glomerulus (Jones et al., 2008).

OSN number estimates derived from TGV may be sufficiently accurate depending on the goals of the study and the number of mice that need to be analyzed. The linearity of this correlation is not entirely surprising but also not obvious. One could have expected that at low and high OSN numbers the curve would flatten out - in particular at lower OSN numbers, as conceivably a fixed minimum volume of a glomerulus could be occupied by non-axonal structures.

Another limitation of our studies is that they are based on mice in the conventional mixed 129 x B6 background, which is currently the best practice. Backcrossing of the targeted mutations to C57BL/6 may help in reducing some of the variability. But as most of OR gene regulation takes place in *cis*, at the promoter level, the regions around the targeted OR locus will always be of 129 origin - in fact, they will continue to be the nucleotide sequences that were present in the genome of the original embryonic stem cell in which the targeted mutation was introduced. New genetic manipulation technologies like CRISPR/Cas9 might generate FP-tagged mutations in a C57BL/6 background. It will then also be possible to compare cell numbers between counting fluorescent cells in FP-tagged strains with counting cells expressing the corresponding unmanipulated OR gene in wild-type C57BL/6 mice by RNA in situ hybridization.

In conclusion, the practical outcome of this empirical study is that TGV is a highly reliable indicator of OSN number.

7 Conditional knockout of Neuropilin-1 in M71-expressing OSNs

7.1 Results

Neuropilin-1 (Nrp1) is expressed in several different types neurons (Gu et al., 2003). As described in Chapter 2.8, Nrp1 is one of the major factors in axonal wiring in the mouse olfactory system. A conditional knockout of Nrp1 (Imai et al., 2009) moves the glomerular position of OSNs, expressing a transgene rat I7 from the MOR23 promoter, to a more anterior position in the bulb. In heterozygous conditional Nrp1 knockout mice, an intermediate position was observed. However Imai and colleagues (2009) used a transgene approach, by random integration of a rat OR (rI7) under the MOR23 promoter somewhere in the genome.

This chapter describes the phenotype of gene-targeted conditional knockout of Nrp1 in M71 OSNs. I found that M71-expressing OSNs that are devoid of Nrp1 form ectopic glomeruli at the anterior tip of the OB but also maintain glomerular coalescence in their typical position in the bulb, comparable to M71-IRES-tauGFP.

7.1.1 Breeding strategy

To study the effects of a conditional knockout of Nrp1 in OSNs, a genetic approach was chosen. The idea is to study axons expressing a certain OR and deficient for Nrp1 and compare them, in the same mouse, to axons expressing the same OR but not deficient for Nrp1. The unusual feature of monoallelic and monogenic expression of an OR gene enabled this strategy. To generate the crosses described in this chapter, gene-targeted strains expressing M71 were chosen because these are some of the most described and characterized strains available. Two Nrp1 conditional knockout alleles were used, resulting in two different strains which both were the result of a triple cross (Figure 7.1). The two conditional Nrp1 alleles are: Nrp1-flox/J was

generated in our lab (unpublished) and npn1-5247 (JR#5247), the same allele as used by Imai and colleagues (2009).

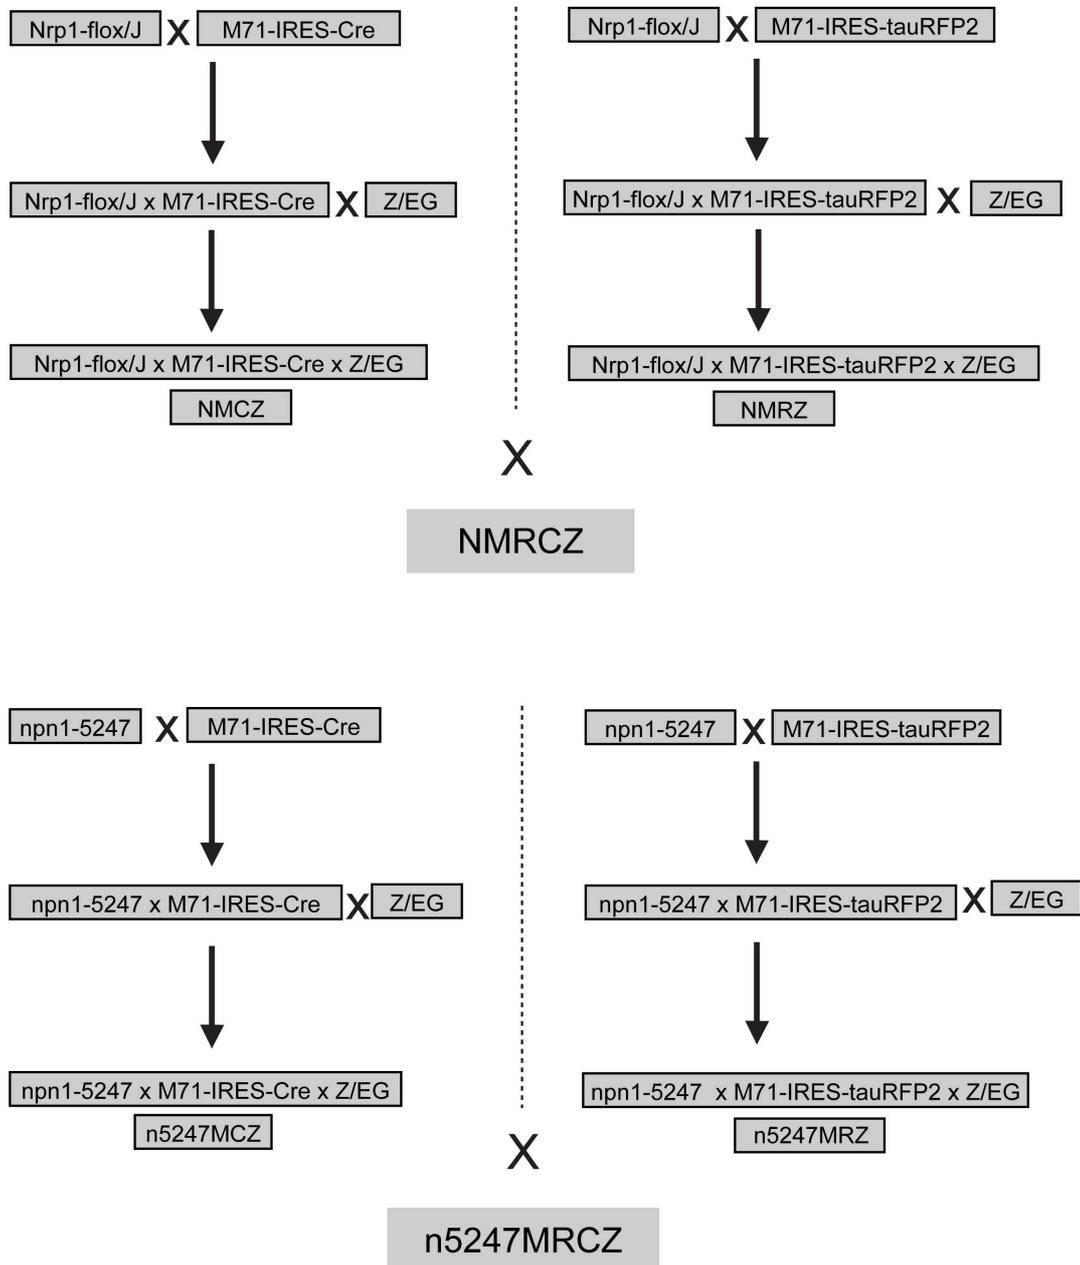

Figure 7.1 Breeding scheme for conditional *Nrp1* knock out strain

This figure illustrates the crosses set up for the *Nrp1* knockout strain. After crossing each strain, the offspring was intercrossed until the cross was homozygous for all genes of interest. Then the next strain was crossed to the previous cross and the process was repeated. The end result was four strains (NMCZ, n5247MCZ) with a conditional knockout of *Nrp1* in M71-expressing neurons (with one of two different conditional alleles for *Nrp1*) and two strains that express normal levels of *Nrp1* (NMRZ, n5247MRZ) where M71 coexpresses RFP2. Mating these crosses results in the desired compound heterozygous strains (NMRCZ, n5247MRCZ) where M71-expressing OSNs expressing *Nrp1* coexist with M71-expressing OSNs not expressing *Nrp1*.

Each of the two crosses contains Nrp1 mutated with loxP sites for conditional knockout and the Z/EG transgene as a reporter for the expression of the Cre recombinase. The difference is the M71-expressing strain crossed to Nrp1-flox and Z/EG:

- crossing to M71-IRES-tauRFP2 should have no effect and should have the same phenotype as M71-IRES-tauRFP2 on its own.

- crossing to M71-IRES-Cre should knockout Nrp1 the loxP-flanked site in Z/EG resulting in conditional Nrp1 knockout phenotype and the expression of GFP.

Crossing the two homozygous triple crosses results in the desired compound heterozygous quadruple mutant strain (Figure 7.2).

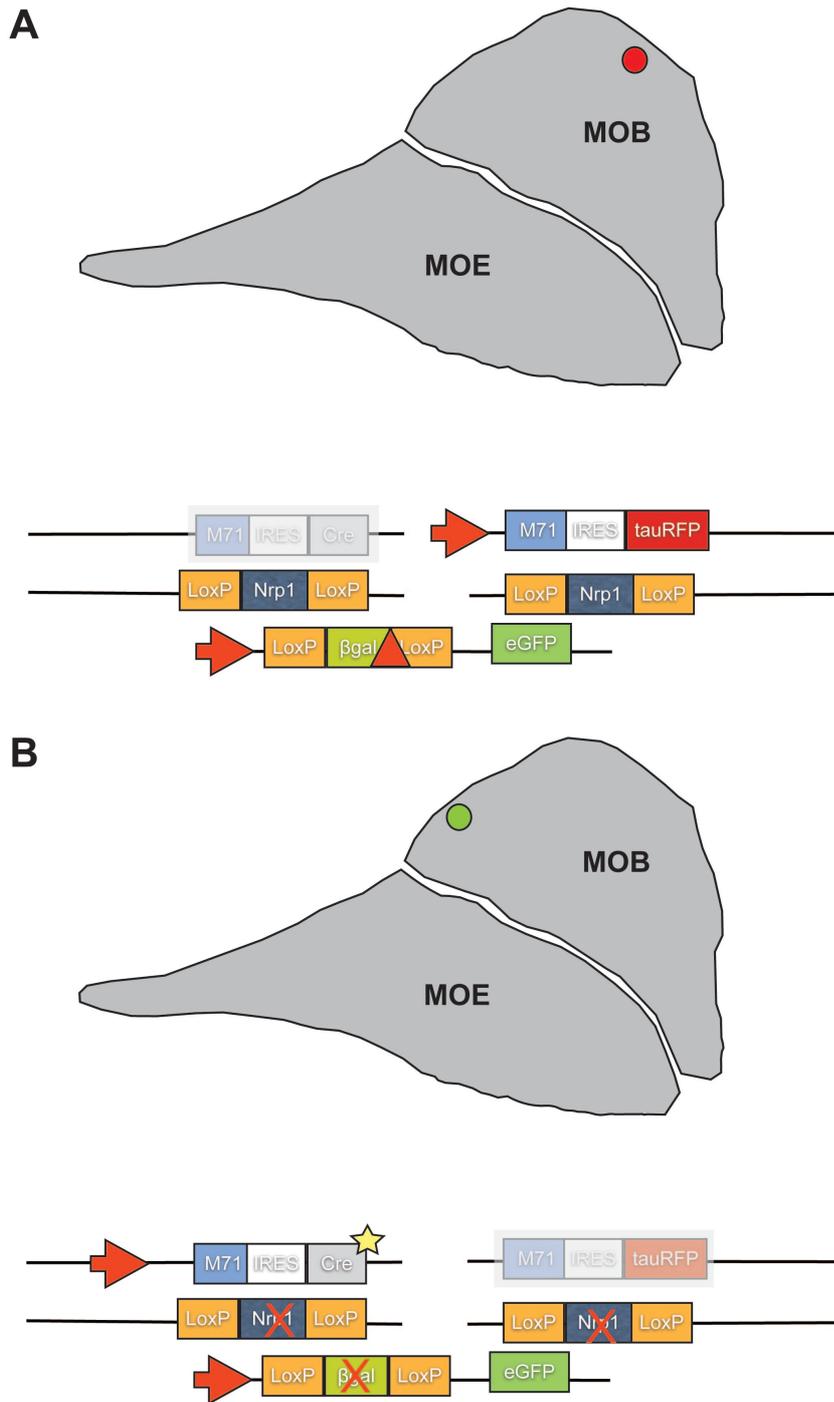

Figure 7.2 Conditional knockout in gene-targeted quadruple mutants

(A) All OSNs expressing the allele M71-IRES-tauRFP2 have normal levels of endogenous Nrp1 expression and coalesce into glomeruli at a position that is typical for M71 glomeruli (red dot). (B) In OSNs expressing the allele M71-IRES-Cre the Cre recombinase is expressed (yellow star) excising Nrp1 and the loxP-flanked β -galactosidase including the stop codon from the Z/EG transgene, enabling GFP expression. These axons coalesce into an ectopic, anterior position (green dot).

7.1.2 Nrp1 knockout

Another cross was created to examine the global effect of Nrp1 on axonal wiring in the mouse olfactory system. The Nrp1-flox strains were crossed to the Z/EG reporter transgene and the OMP-Cre strain. OMP, the olfactory marker protein, is expressed in all mature OSNs. In the OMP-Cre strain, the OMP coding sequence is replaced with the Cre recombinase. The knockout of Nrp1 in all mature OSNs has no discernible overall effect on axonal wiring. The glomeruli are formed apparently normally, and the glomerular layer lacks Nrp1 staining for Nrp1 antibody (Figure 7.3).

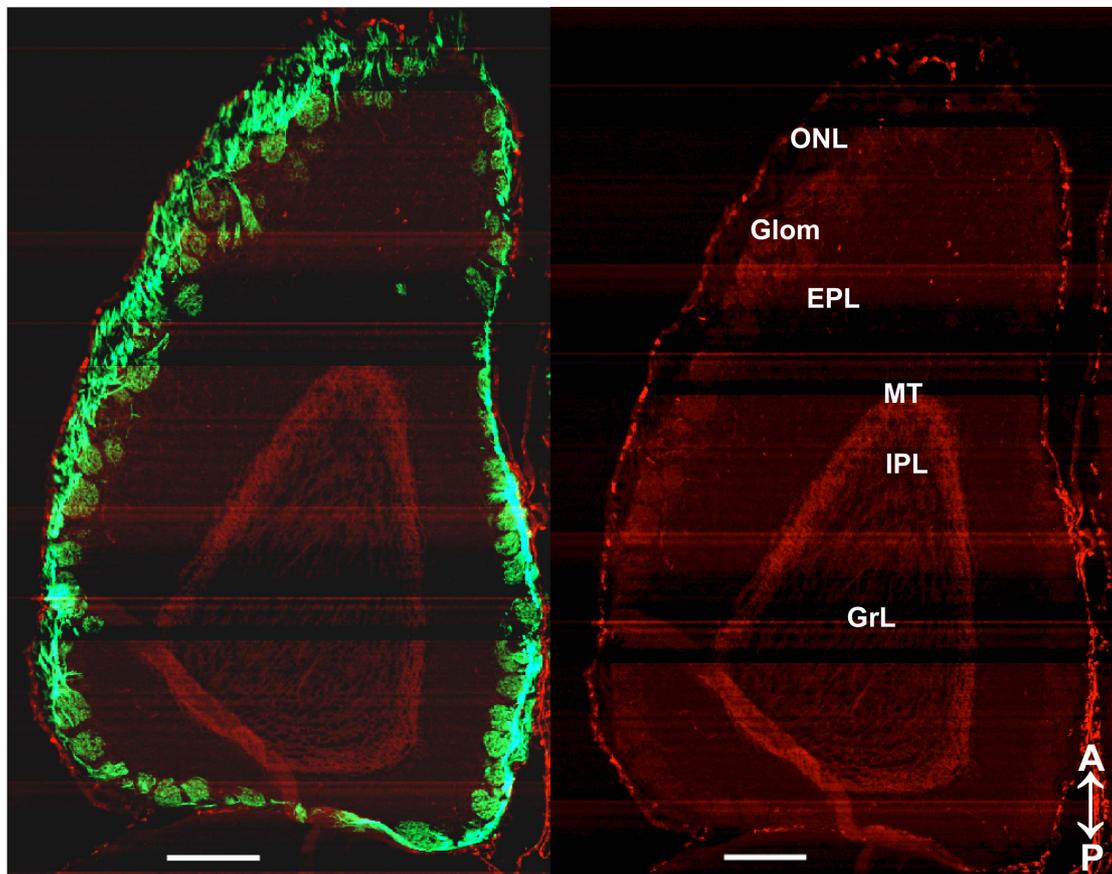

Figure 7.3 Nrp1 knockout in OMP-expressing OSNs

Horizontal section of PD21 olfactory bulb taken with the Aperio Scanscope shows intrinsic fluorescence of OMP-Cre x Z/EG expressing neurons (green) and antibody staining for Nrp1 (red). The distribution, size and form are similar to glomeruli expressing Nrp1. The right image illustrates the different layers of the olfactory bulb: Olfactory nerve layer (PNL), glomerular layer (Glom), external plexiform layer (EPL), mitral cell layer (MT), internal plexiform layer (IPL) and granule layer (GrL). Only background Nrp1 staining is detected in the glomerular layer of knockout strain (Scale bar: 250 μ m).

Although the axonal wiring seems to be not affected by a knockout of Nrp1 in OMP-expressing neurons, antibody staining shows a lack of staining for Nrp1 in the glomerular layer of the OB compared to strains with normal expression of Nrp1 (Figure 7.4). The antibody staining for Nrp1 in NOCZ mice confirms the effectiveness of the conditional Nrp1 knock out using Nrp1-flox/J.

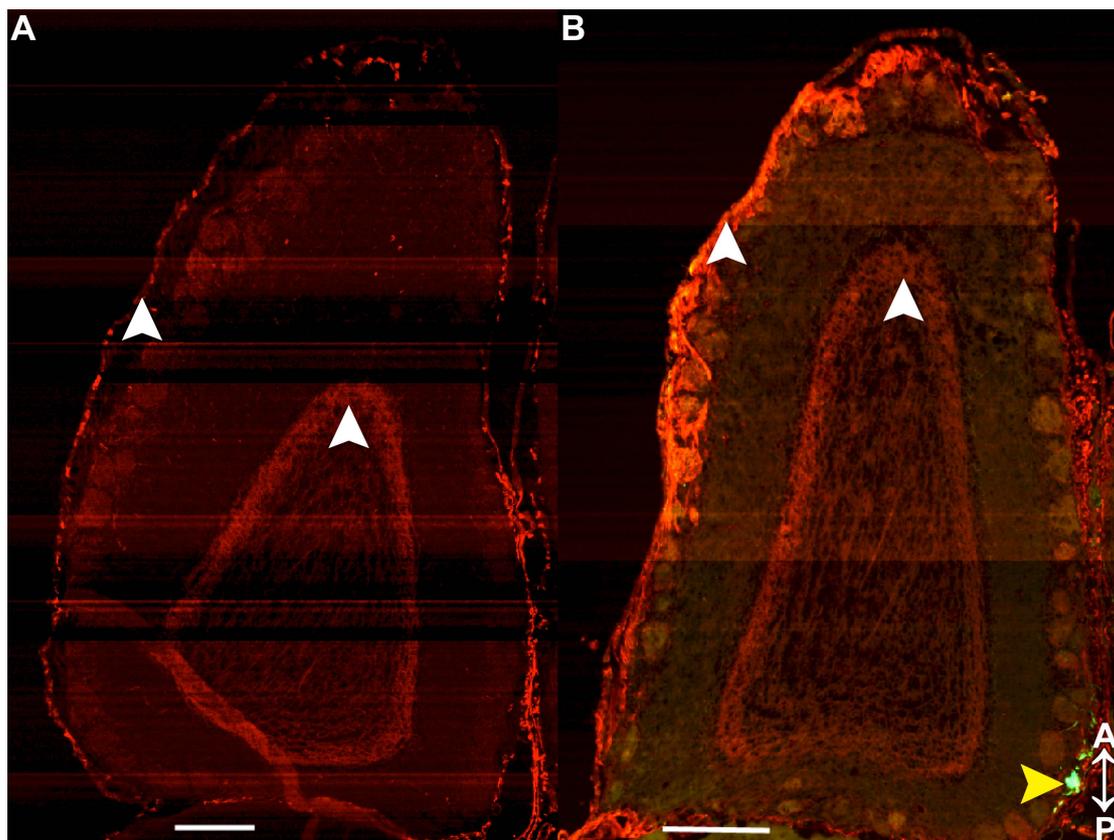

Figure 7.4 Comparison of Nrp1 expression

Horizontal section of PD21 olfactory bulb taken with the Aperio Scanscope compares intensity of Nrp1 antibody staining (red) in mice with an knockout of Nrp1 in OMP-expressing OSNs (A) compared to staining intensity in mice with normal Nrp1-expression (B, M71-IRES-Cre x R26-STO τ GFP). White arrowheads indicate that Nrp1 is still expressed in the knockout in layers other than glomerular layer. Green signal in B references the medial glomerular position of M71-IRES-Cre expressing OSNs (yellow arrowhead). Scale bars: 250 μ m.

7.1.3 Ectopic glomerulus

The phenotype of the Nrp1 knockout in M71-expressing OSNs is a robust and consistent observation in all analyses. A new glomerulus is formed on the medial side in the dorsal anterior bulb. However there are still labeled axons converging onto glomeruli in the posterior area of the OB. In general a

singular glomerulus is formed in a dorsal, central area between the medial and lateral position of the normal M71 glomeruli (Figure 7.5). Often an additional glomerulus is formed in the dorsal medial area close to the area normally occupied by M71-expressing axons.

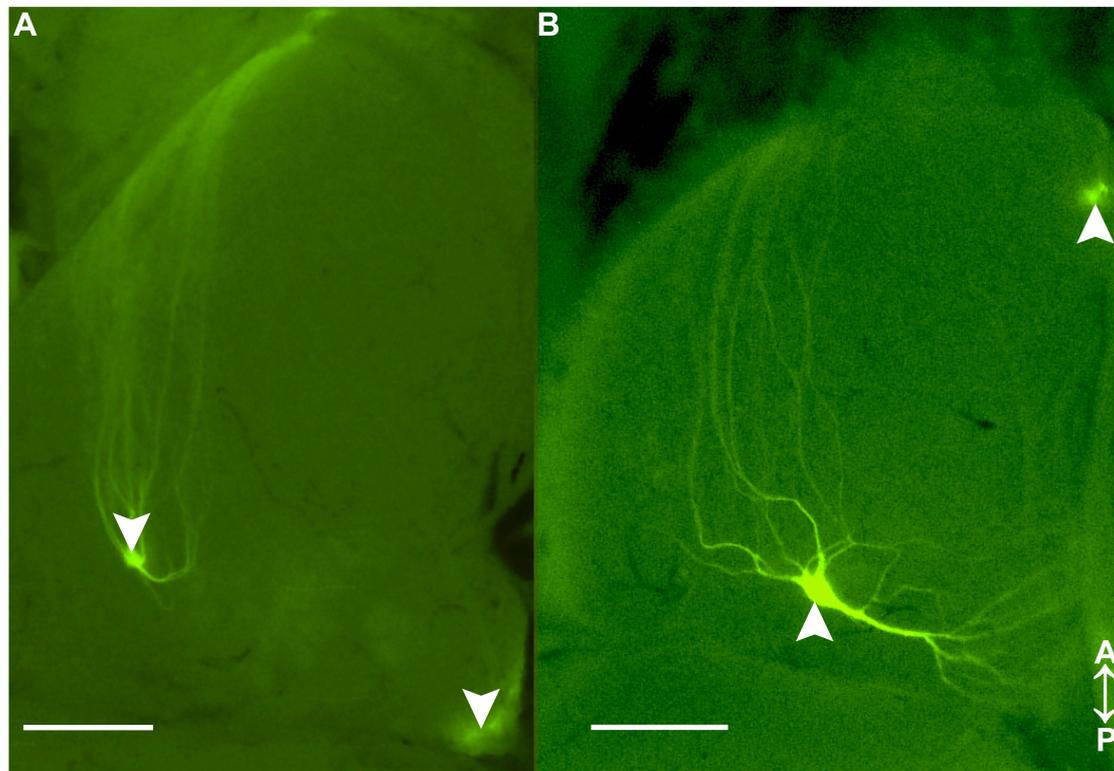

Figure 7.5 Comparison of M71 strains for Nrp1 knockout

(A) Dorsal view of a whole mount of a M71-IRES-Cre x R26-tauGFP PD21 bulb, imaged with NIKON, showing the intrinsic fluorescence. White arrowheads show normal glomerular positions for M71-expressing OSNs. (B) Dorsal view of a n5247MCZ PD21 bulb showing intrinsic fluorescence. White arrowheads show ectopic glomeruli for Nrp1 negative M71 axons. Scale bars: 500 μ m.

7.1.4 Mixed glomeruli in conserved glomerular position

The phenotypes of the ectopic anterior glomeruli in dorsal medial position as well as of the shifted lateral glomeruli are conserved in all knockout strains. For more details on the axon composition of the glomeruli of the NMRCZ compound heterozygous animals, 12 μ m coronal sections of the bulb at PD21 and PD70 were taken.

The posterior glomeruli in conserved medial M71 position in the NMRCZ strain are heterozygous for the M71 alleles. The shifted glomeruli, which are along the anterior-posterior axis at the same height as the normal M71 glomerular position, are shifted more dorsally and often appear to be

fragmented into several small glomeruli (Figure 7.6). If a glomerulus is formed at the normal M71 position, it is heterozygous for Nrp1-deficient axons and M71 axons with normal Nrp1 expression.

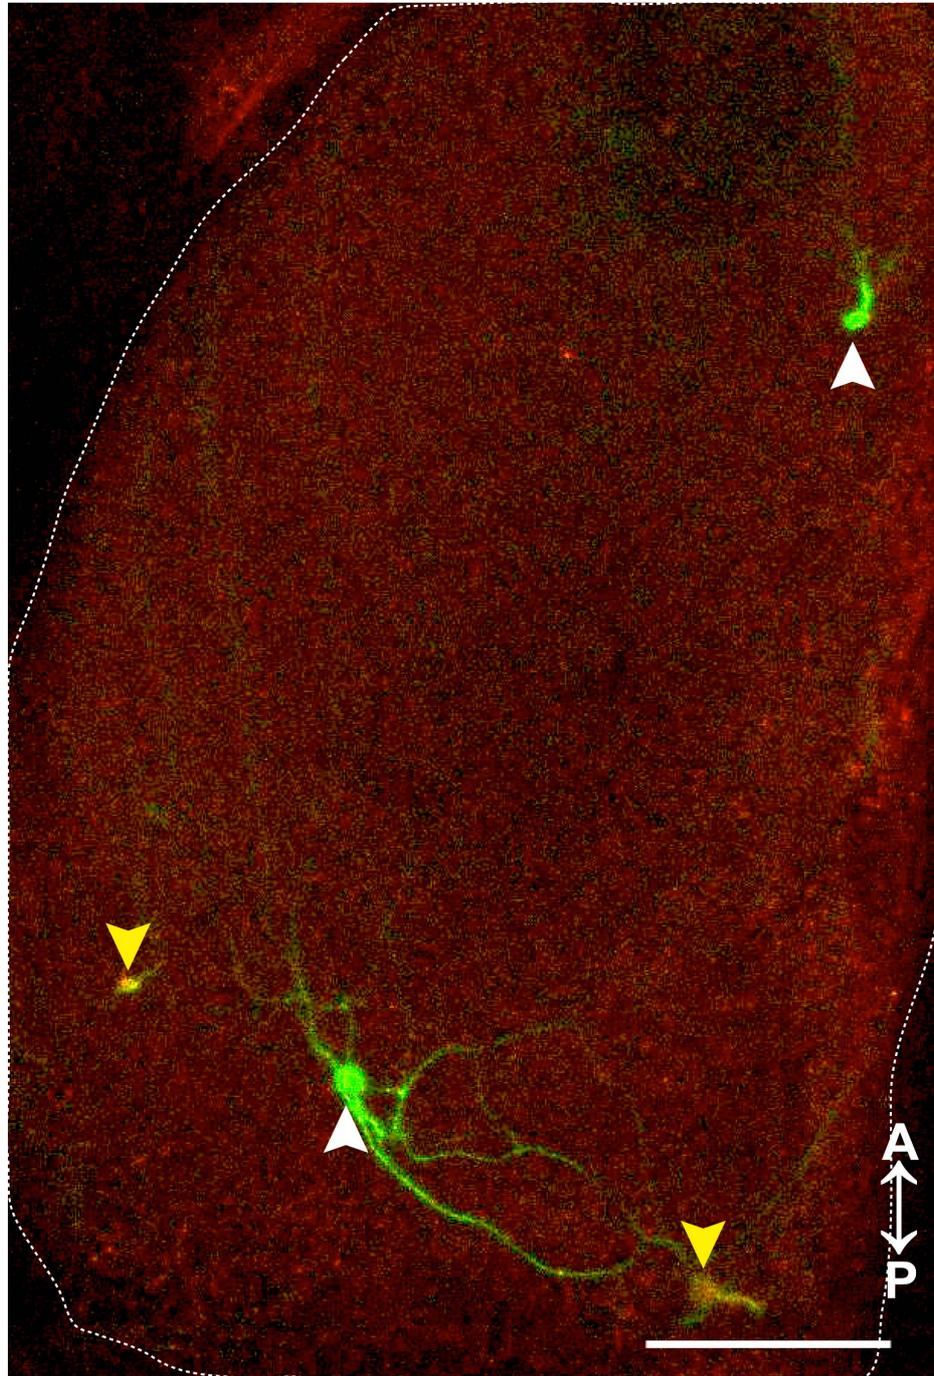

Figure 7.6 Axonal wiring in a whole mount NMRCZ mouse

Confocal image of a whole mount of a PD14 NMRCZ mouse. White arrowheads indicate ectopic glomeruli only formed by M71 axons deficient of Nrp1 (intrinsic fluorescence, green). Yellow arrowheads indicate heterozygous glomeruli at the normal M71 glomerular position, consisting of Nrp1-deficient axons and axons with normal Nrp1 expression (intrinsic fluorescence, green; Nrp1, red). White dashed line shows the outline of the olfactory bulb. Scale bar: 500 μm .

In the heterozygous glomeruli both axons intermingle, only in one single NMRCZ mouse a compartmentalization was observed at PD70 (Figure 7.7). This glomerulus shows the different Nrp1 expression levels for the M71 alleles.

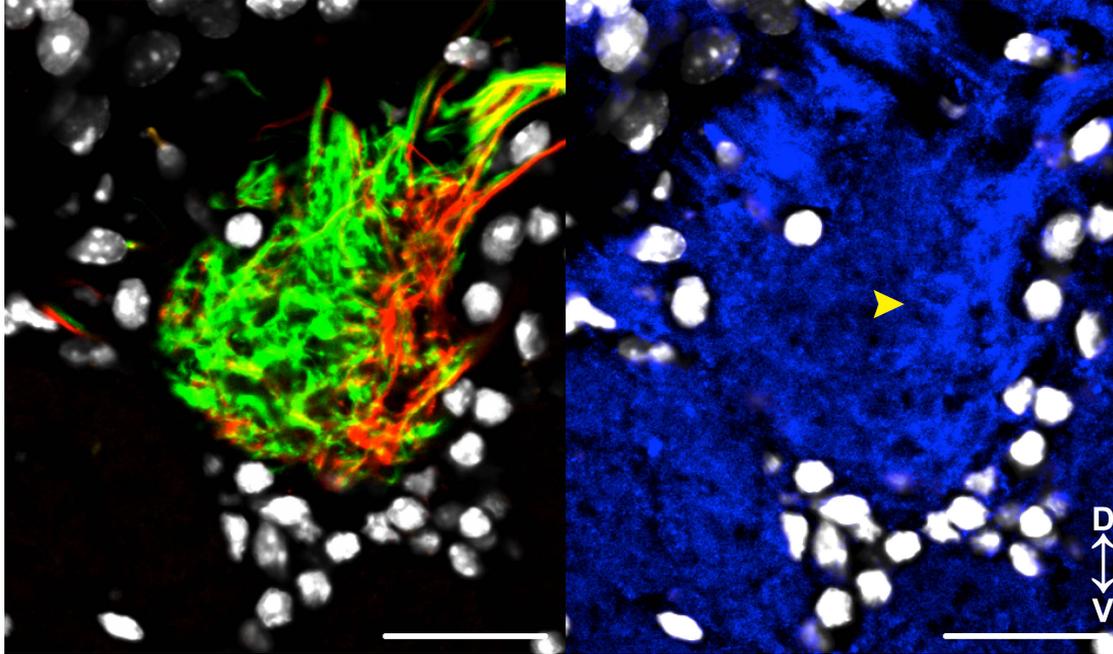

Figure 7.7 Heterozygous NMRCZ medial glomerulus

The left image shows 12 µm coronal section of a NMRCZ mouse at PD70 and axons of both M71 alleles forming a heterozygous glomerulus with Nrp1 deficient axons (intrinsic fluorescence, green) and axons with normal Nrp1 expression (antibody staining for tauRFP2, red). The right image shows the Nrp1 antibody staining in the same glomerulus (blue). A stronger staining for Nrp1 is clearly visible (yellow arrow) at positions occupied by the red axons in the left figure with normal Nrp1 expression. Scale bar: 25 µm.

For all mice analyzed, the ectopic anterior glomeruli consist of GFP stained M71 OSNs, which show only background levels of Nrp1 antibody staining (Figure 7.8).

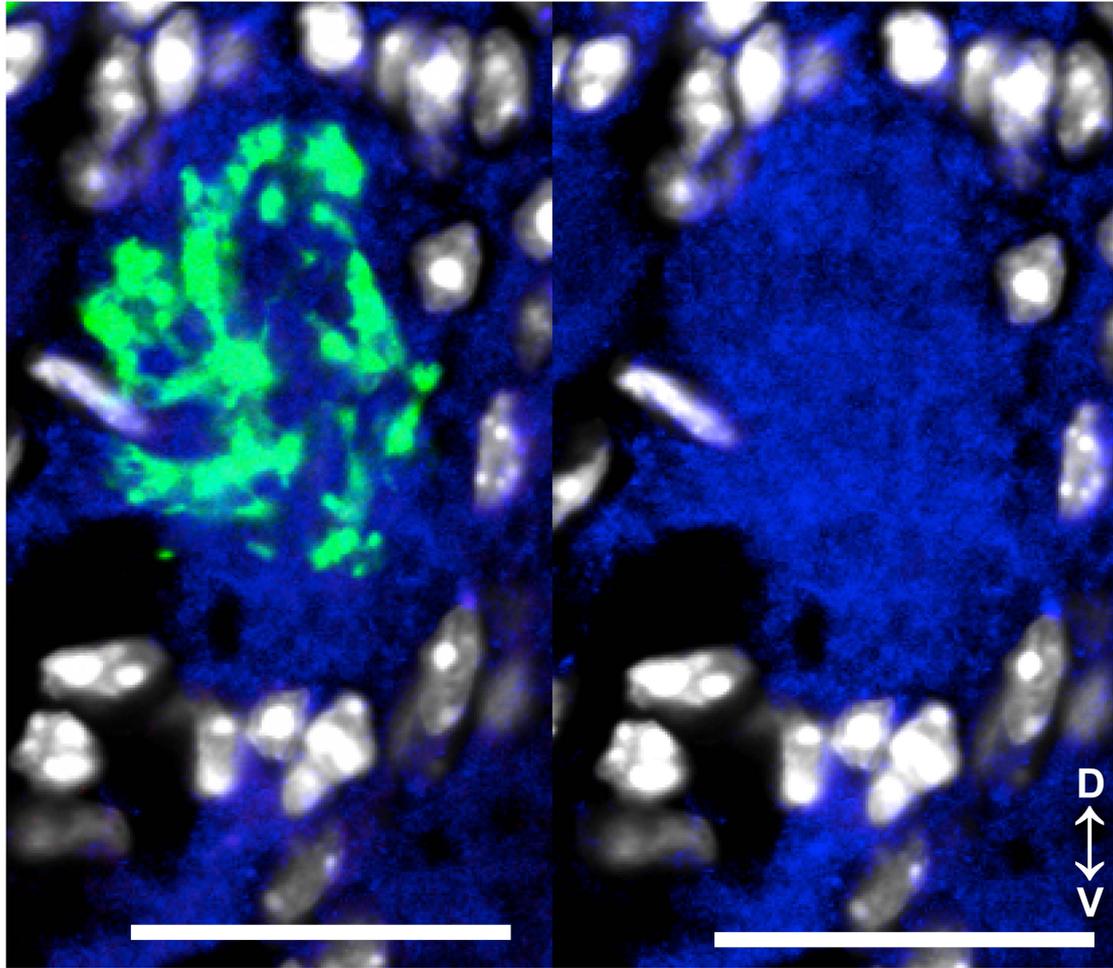

Figure 7.8 M71 OSN ectopic glomerulus

Coronal section of a PD70 ectopic glomerulus of the NMRCZ strain (12 μm thickness). The green M71-IRES-Cre expressing axons form small homogeneous ectopic glomeruli (intrinsic fluorescence, left) while the Nrp1 antibody staining (blue) in that glomerulus is absent from the green axons (right). Scale bar: 25 μm

7.1.5 Nrp1 knock out phenotype at various ages

The phenotype of ectopic anterior glomerulus starts forming directly after birth in n5247MCZ mice. Axons project to the anterior ectopic position as well as to the posterior, normal M71 glomerular position (Figure 7.9).

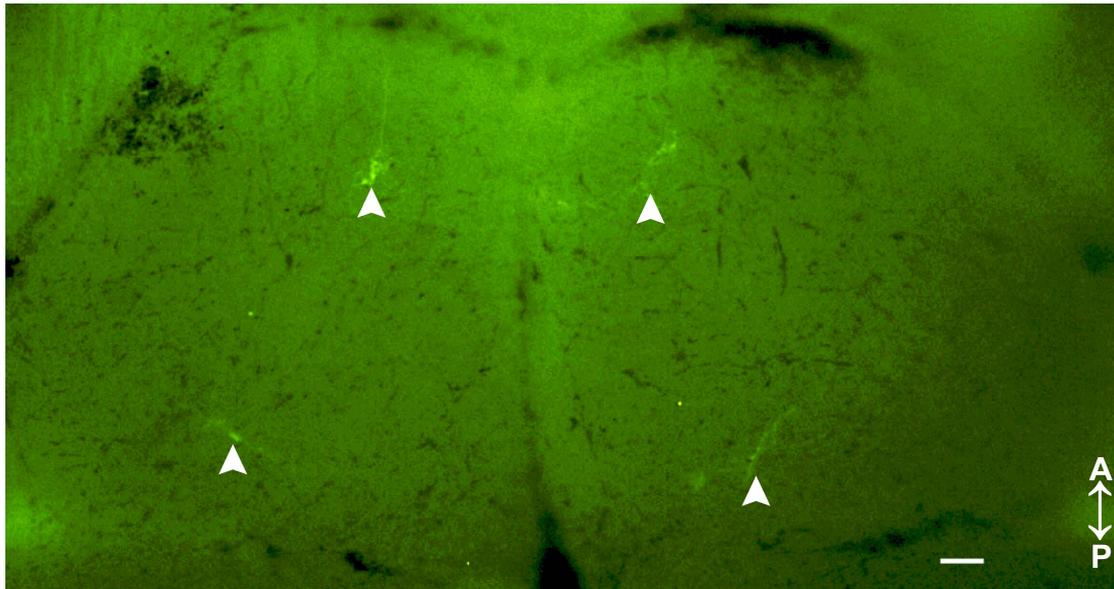

Figure 7.9 Axonal wiring of n5247MCZ mice in neonatal mice

Dorsal view of a whole mount of a PD0 n5247MCZ mouse. The white arrowheads show nascent glomeruli forming at the ectopic anterior position and the posterior, normal M71 position. Glomeruli are not fully formed yet but already project to the position typical for this phenotype. Scale bar: 100 μ m.

Likewise the Nrp1 knockout phenotype remains well conserved at PD140 (Figure 7.10). The ectopic glomeruli are still present and a posterior medial glomerulus is maintained at the normal M71 medial position. The lateral posterior glomerulus is shifted more dorsally and dispersed into several small glomeruli compared to M71.

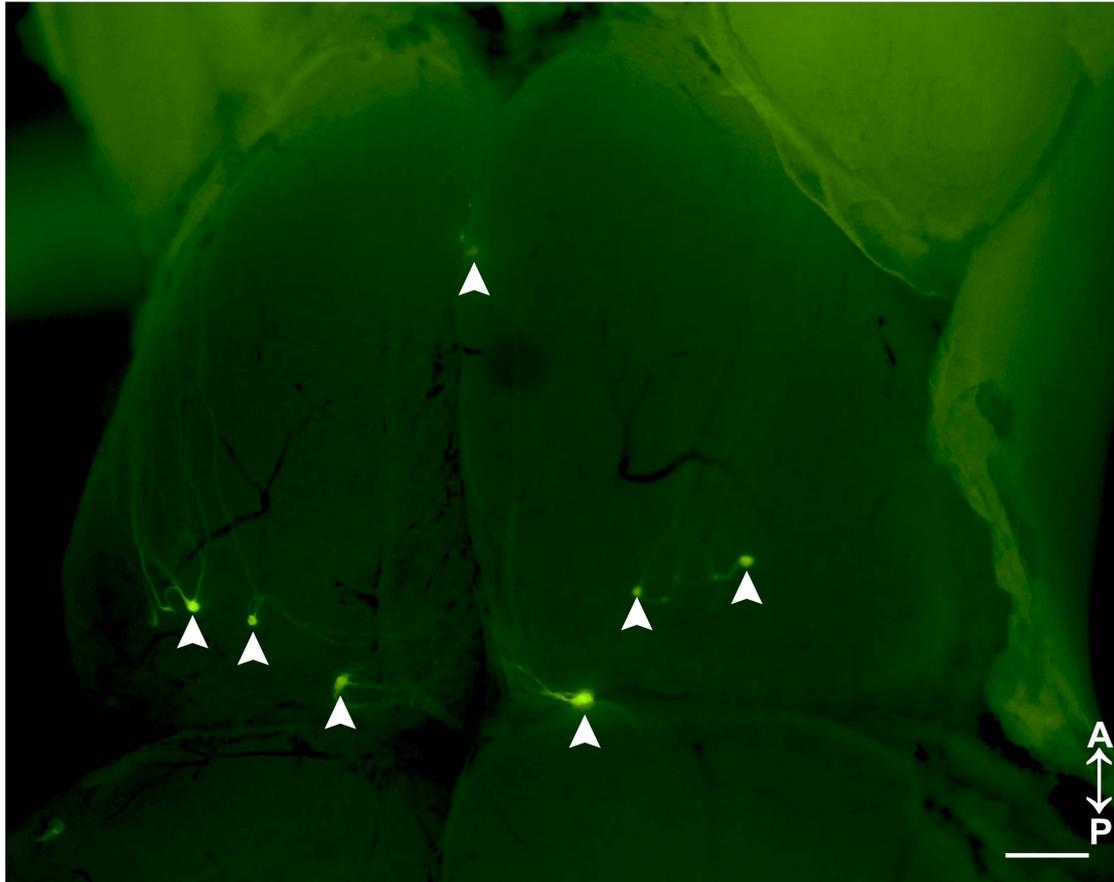

Figure 7.10 Axonal wiring in old NMRCZ mice

Dorsal view of a whole mount the olfactory bulb of a NMRCZ PD140 mouse taken with NIKON stereoscope. White arrowheads indicate glomeruli formed by M71-expressing axons deficient for Nrp1 (intrinsic fluorescence, green). Axons of M71-expressing OSNs with normal Nrp1 expression are not shown in this image. Scale bar: 500 μ m

To evaluate for the stability of the phenotype through life, several age groups were chosen for analysis. The compound heterozygous knockout strain NMRCZ was analyzed at young age of PD7, PD14 (the same age as the mice reported by Imai *et al.* (2009)) and PD21, in young adults at PD35 and adults at PD70, and finally in aged mice at PD140. In each age group the reported phenotype is present and well conserved (Table 7.1).

For the homozygous knockout strain n5247MCZ the age PD21 as the lab standard age and PD0 were analyzed. These also show the phenotype (Table 7.1).

Table 7.1 Table of age and number of mice investigated for Nrp1 knock out strain

Strains	PD0	PD7	PD14	PD21	PD35	PD70	PD140
NMRCZ		Ectopic anterior glomeruli Mixed medial posterior glomeruli Ectopic pos. med. Glomeruli	Ectopic anterior glomeruli Mixed medial posterior glomeruli Ectopic pos. med. Glomeruli	Ectopic anterior glomeruli Mixed medial posterior glomeruli Ectopic pos. med. Glomeruli	Ectopic anterior glomeruli Mixed medial posterior glomeruli Ectopic pos. med. Glomeruli	Ectopic anterior glomeruli Mixed medial posterior glomeruli Ectopic pos. med. Glomeruli	Ectopic anterior glomeruli Mixed medial posterior glomeruli Ectopic pos. med. Glomeruli
Numbers		7	7	6	5	5	2

Numbers	3			7			

7.1.6 Control experiments

To test if the knockout of Nrp1 has an effect on OSN numbers, mice from the NMRCZ strain (n=4) and n5247MCZ (n=3) strain were perfused at PD21 and cells were counted as described in Chapter 4.9. There was no significant difference between NMRCZ (t-test, p=0.053), n5247MCZ (t-test, p= 0.76) and M71-IRES-tauGFP mice (Figure 7.11). In the case of NMRCZ cells expressing either allele were evaluated separately and there was no significant difference between the OSN numbers between the two alleles (t-test, p=0.85); each contributing half to the total OSN number of the NMRCZ strain, in keeping with the monoallelic property of an OSN.

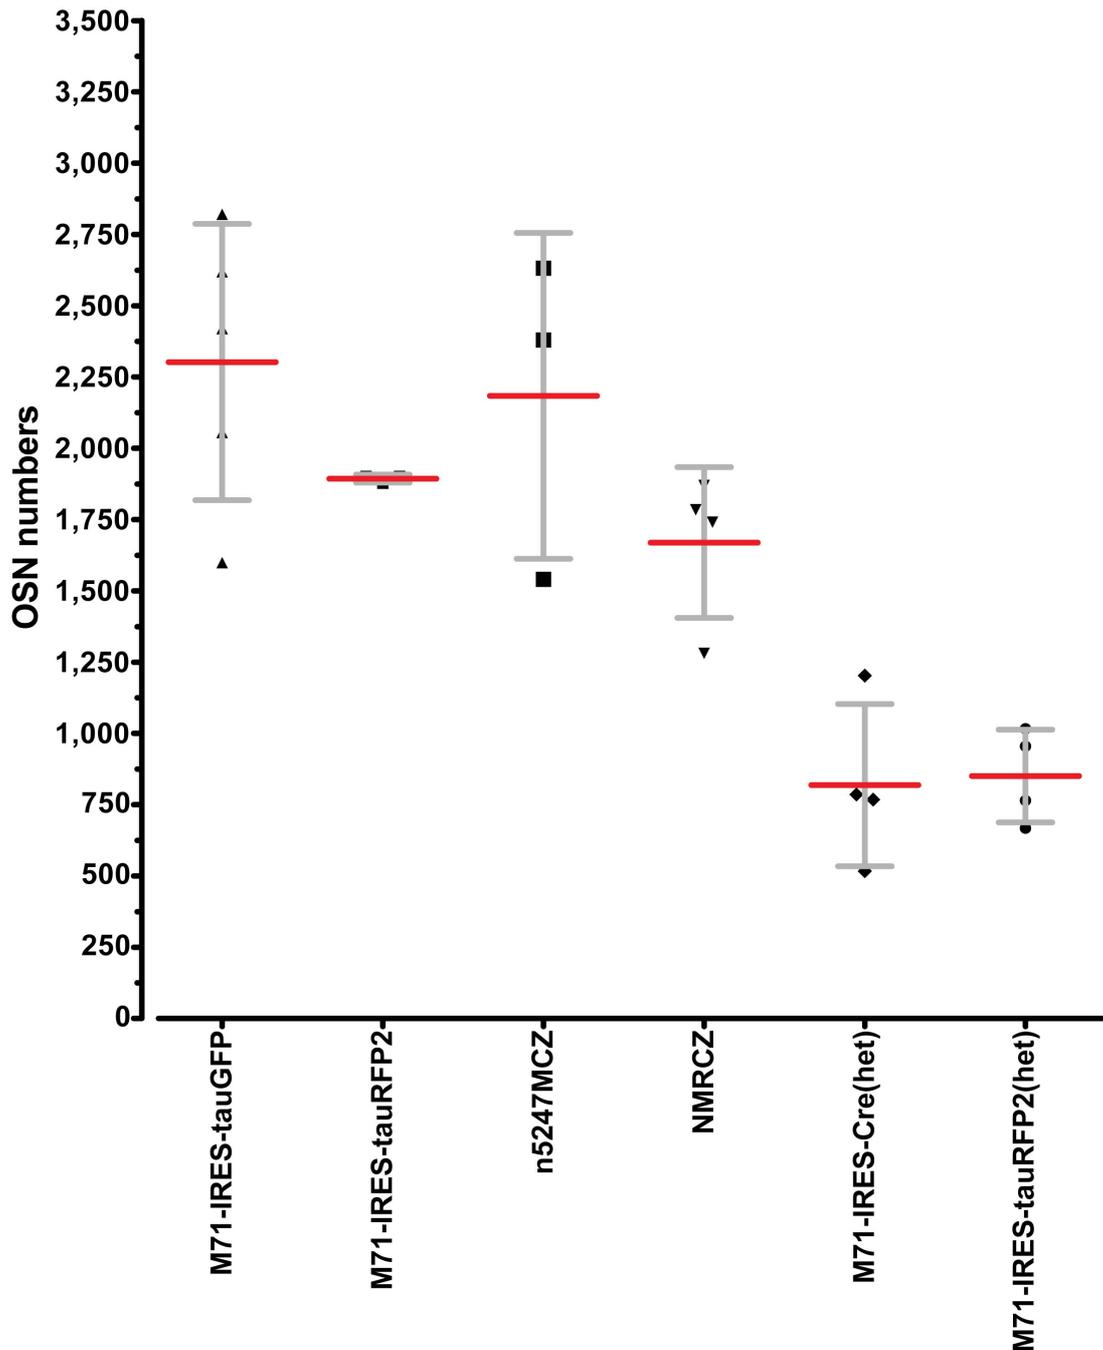

Figure 7.11 OSN numbers for Nrp1 knockout strains

OSN numbers of PD21 Nrp1 knockout strains (\pm SD). Each symbol represents a single mouse. M71-IRES-tauGFP and M71-IRES-tauRFP2 are the same data as reported in Chapter 6 for comparison. M71-IRES-Cre(het) and M71-IRES-tauRFP2(het) are the OSNs for the individual M71 alleles of NMRCZ, added together totally in the NMRCZ results.

7.2 Discussion

Axonal wiring in the mouse olfactory system remains poorly understood a quarter century after the discovery of OR genes. One of the most impressive feats of the olfactory system is its ability to establish and maintain conserved

glomeruli homogeneous for axons expressing a specific OR in the olfactory bulb, given there are around 1,100 different OSN types. Gradients of cell adhesion molecules are one of several possible explanations for the mechanism of the precise axonal wiring, with Nrp1 being one of the most prominent members. A popular model attributes the glomerular position along the anterior-posterior axis of the olfactory bulb to an increasing gradient of Nrp1 along this axis (Imai et al., 2009). Nakashima et al., 2013 link the expression of Nrp1 to the basal activity of the OR expressed in the OSNs. The higher basal activity in developing OSNs is translated with a signal transduction cascade to a stronger expression of Nrp1 and thus a more posterior position in the OB. However Schwarting et al. (Pasterkamp et al., 1998) reported antibody stainings in rat that show that Nrp1 is not expressed in a simple gradient along the anterior-posterior axis and that the repulsive ligand for Nrp1, Semaphorin 3A (Sema3A), is expressed in a lateral and medial area of the bulb (Schwarting et al., 2004).

The results reported in this chapter also show that the axonal wiring along the anterior-posterior axis is not simply dependent on a Nrp1 gradient. A conditional knockout of Nrp1 in M71-expressing OSNs results in a stable phenotype, where the normal two dorsal posterior M71 glomeruli per bulb (one medial, one lateral) in most cases still exist but other small ectopic glomeruli are formed in addition. Most prominent and stable is the ectopic glomerulus at the anterior tip of the OB. As this ectopic glomerulus this also formed in mice with a homozygous conditional knockout of Nrp1 in M71-expressing OSNs, it is unlikely that the axons with normal Nrp1 expression in the compound heterozygous mice somehow rescue the Nrp1-deficient axons. I speculate that the axons with normal Nrp1 expression help to stabilize the glomeruli at the normal M71 position, because they appear more often in the NMRCZ strain than in n5247MCZ mice. Using a gene-targeting approach these strains are closer to the wild-type situation than transgenic mice. It appears that other factors are also involved in determining the position of a glomerulus. Nrp1 is definitely an important factor in axonal wiring in the OB but it is not the only one, at least for M71.

Another interesting observation is that the phenotype is remarkably similar to a conditional knockout of the adenylyl cyclase 3 (AC3) in OSNs. Both studies, one investigating the axons in M72 mice (Col et al., 2007) and the other one those in M71 mice (Zou et al., 2007), show a similar phenotype of an ectopic glomeruli at the anterior tip of the bulb. Both strains are closely related and axons of their OSNs terminate in the same area of the bulb. In most instances the glomeruli of M71 and M72 are adjacent. As M72 has a higher number of OSNs than M71 (Chapter 6) an additional ectopic glomerulus on the lateral side may be able to form stable in the lateral half (Col et al., 2007).

The similarity of the AC3 knockout phenotype and the phenotype of Nrp1 knockout strongly suggests that the signal transduction cascade mediated by cyclic AMP (cAMP) is an important factor in the expression of Nrp1. Normally Nrp1 does not use cAMP as a second messenger but perhaps another unknown factor is regulated by cAMP. It is possible that this factor is responsible for the complex task to sort 1,100 different kinds of axons into glomeruli at conserved positions, and that this factor is somehow regulated by Nrp1.

In summary the two Nrp1 knockout strains reported in this chapter have an interesting phenotype similar to the effect that an AC3 knockout has on M71-expressing OSNs but unlike the conditional knockout in a transgene mouse reported by Imai and colleagues (2006).

8 Final Discussion

In this thesis I have studied several aspects of the complex mechanisms of axonal wiring in the mouse olfactory system. I set out originally to determine the effect of caGs in M71-expressing OSNs by generating novel strains of gene-targeted strains. My guess is that it would not have shifted the position of M71 glomeruli further posteriorly. However due to persistent difficulties of generating an appropriate targeting vector and because of time constraints I did not continue this project and focussed on the two other aspects reported here.

The second project was a comprehensive empirical study of the distribution and number of OSNs in the olfactory epithelium. Such a study has not been conducted before, and became only possible because of the fortune of a large collection of gene-targeted strains coexpressing tauGFP with individual ORs in the lab. This resource enabled a broad insight into the fundamental constituents (OSNs and glomeruli) of axonal wiring, showing the strong correlation between the two. It also quantified and showed possible pitfalls of sampling of OSN numbers, with determining sampling errors for the strains, showing their different expression patterns and determining the stability of OSN numbers in each strain. My results indicate that OSNs expressing MOR23 should be used for further, quantitative studies because of the stability of this population.

In the third project the role of Nrp1 in axonal wiring was investigated. Recent studies support a direct effect of a Nrp1 gradient on glomerular position along the anterior-posterior axis of the olfactory bulb, but these studies could not explain satisfactorily the monumental task of sorting ~1,100 populations of OSNs so neatly and precisely into glomeruli. The results of a conditional knockout of Nrp1 in M71-expressing OSNs reveal that a simple gradient of Nrp1 cannot be the only factor that determines the anterior-posterior position of a glomerulus. Surveying the research done on axonal wiring in the mouse olfactory system I favour the model of a zip code. Several

molecules contain part of the information to which region within in the glomerular layer the axon has to grow. With the knockout of one molecule or of one signalling cascade, in this case Nrp1 or AC3, axons projected additionally to ectopic positions due to the distorted code.

In conclusion I was able to contribute basic and quantitative empirical data for further research to build upon. I also provided some interesting insights into one of the many aspects of the complex and fascinating mechanism of axonal wiring: Nrp1 is an important factor for OSN axonal pathfinding, however, the mechanism is more complex and a simple gradient of the expression of Nrp1 cannot explain the findings.

pBluescript Phagemid Vector (2015)

<http://www.genomics.agilent.com/GenericB.aspx?PageType=Vector&SubPageType=Vector&PageID=32>

11 Acknowledgements

I would like to thank Dr. Peter Mombaerts for giving me the opportunity to work in his lab and on such versatile projects. His support, his belief in the projects, his scholarly advice and the inspiring discussions made this thesis possible.

I would like to thank Professor Bodo Laube for being my contact to the TUD and guiding me through this thesis. Even at a distance he was always supportive. His scholarly advice and fruitful discussions and open ears for my worries helped a lot.

I would like to thank Professor Paul G. Layer, for agreeing to evaluate this thesis and for his scholarly advice in the process.

A great thanks goes to my supervisor Dr. Mona Khan. Her advice, training, guidance and long discussions helped substantially for writing this thesis. Thank you for always taking the time for me.

Another great thanks goes to Dr. Martin Vogel. Thanks you for being always helpful and supportive. You are not only a good colleague but also a good friend.

I would also like to thank the members of the Max Planck Research Unit for Neurogenetic (Guido, Elisabeth, Isabelle, Diane, Bartos, Christian, Anna H., Anna D., Andrea, Markela, Marta, Mario, Maria, Masayo, Bolek, Kia, Evelien, Florian, Tobias, Zhaodai, Jiangwei, Zheng, Bassim, Sachiko, Alex, Jan and Vicky) for all their timely helpful advice and unconditional support for my research. A special thanks to the animal caretakers Rebecca L., Rebecca W., Steffi, Mandy, Caroline, Annelie and Ali for helping in handling all the various mice strains and advising me in breeding strategies.

Last but not least I would like to thank my family and friends. I wouldn't have made it without the unconditional support from my parents. Thank you for listening to my science rambling. Also thank you to my friends for keeping up with me during the stressful periods in research and writing. Especially thanks to Christine for support and advice on writing and Damaris for cheering me up when work got tough.

Thank you all.

12 Ehrenwörtliche Erklärung:

Ich erkläre hiermit ehrenwörtlich, dass ich die vorliegende Arbeit entsprechend den Regeln guter wissenschaftlicher Praxis selbstständig und ohne unzulässige Hilfe Dritter angefertigt habe.

Sämtliche aus fremden Quellen direkt oder indirekt übernommenen Gedanken sowie sämtliche von Anderen direkt oder indirekt übernommenen Daten, Techniken und Materialien sind als solche kenntlich gemacht. Die Arbeit wurde bisher bei keiner anderen Hochschule zu Prüfungszwecken eingereicht.

Olaf Christian Bressel

Darmstadt, den

13 Curriculum vitae

1. **Family name** Bressel
2. **First name** Olaf Christian
3. **Date of birth** October 16, 1982
4. **Nationality** German
5. **Civil status** Not married

6. **Education** Elementary school,
Prälat-Diehl-Schule Groß-Gerau, German “Gymnasium“
leaving certificated with “Abitur”
Student of Biology at the Technische Universität Darmstadt

7. **Language skills** German (mother tongue), English (good), Latin (good)

8. **Present position** Ph.D. student at the Max Planck Research Unit for
Neurogenetics since November 2009 in cooperation with TU
Darmstadt

9. **Key qualifications** Advanced practicum in genetics
Advanced practicum in animal physiology, partial at the Max
Planck Institute for Brain Research, Frankfurt, Germany
Advanced practicum in plant physiology
2.5 months lab practicum at University of New South Wales,
Sydney, Australia
8 months diploma thesis at University of New South Wales,
Sydney Australia
Graduated the Preliminary Diploma Examination at Semester 4
Graduated

10. **Professional experience record**
Practicum at the Institute of Pathology, Darmstadt, 2 weeks
Part-time IT-Job, Dresdner Bank Frankfurt, 3 weeks
German army, 9 months, Pioneer “Obergefreiter”, 2 medals for
disaster aid
Part-time job retail Games Workshop, Frankfurt, 5 years
Proxy project leader for S1 Security at Max Research Unit for
Neurogenetics (since 2015)

11. **Others** archery, roleplaying
