## Biochemical FKBP12 Binding Assay

The Ki-value of compound 1 was determined by using a fluorescence polarization assay as described earlier. Therefore, a serial dilution of compound 1 or FK506 in assay buffer ( 20 mM HEPES pH 8.0, 20 $\mathrm{mM} \mathrm{NaCl}, 0.002 \%$ Triton X-100) was placed in a 384 well micro titer plate and supplemented with a mixture of purified FKBP12 and the fluorescent tracer [4.3.1]-16g yielding final concentrations of 1 nM and 0.5 nM . After an incubation of 30 minutes at $25^{\circ} \mathrm{C}$ the fluorescence polarization was determined on a mirco plate reader using an excitation wavelength of 535 nm and an emission wavelength of 590 nm . The obtained data was plotted against the compound concentration and fitted to a competitive binding model yielding the Ki-value of the compounds.

## General Experimental

Reactions were performed in heatgun-dried flasks under an argon atmosphere. All reagents purchased from commercial sources were used directly without further purification.
${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ spectra were recorded at the Department of Chemistry and Pharmacy, Ludwig Maximilians University München on a Bruker AC 300, a Bruker XL 400, or a Bruker AMX 600 at room temperature unless otherwise specified. Chemical shifts are given in ppm ( $\delta$ ). Residual peaks of the deuterated solvents indicated were used as internal standard. The coupling constants ( $J$ ) are given in Hertz (Hz). The following abbreviations are used for the characterization of the multiplicity of the signals: singlet ( s ), singlet broad ( $\mathrm{s}_{\mathrm{br}}$ ), doublet ( d ), triplet ( t ), quartet ( q ) multiplet ( m ) and centered multiplet ( $\mathrm{m}_{\mathrm{c}}$ ).

Mass spectra ( $\mathrm{m} / \mathrm{z}$ ) were obtained on a Thermo Finnigan LCQ DECA XP Plus mass spectrometer at the Max Planck Institute of Psychiatry München, while the high resolution mass spectrometry was carried out at Max Planck Institute of Biochemistry München on a Bruker micrOTOF LC mass spectrometer.

Thin-layer chromatography (TLC) was performed on precoated silica gel F-254 plates from Merck. The spots were visualized by UV light and/or by staining of the TLC plate with potassium permanganate stain ( $1.5 \mathrm{~g} \mathrm{KMnO}_{4}, 10 \mathrm{~g} \mathrm{~K}_{2} \mathrm{CO}_{3}, 1.25 \mathrm{~mL} 10 \% \mathrm{NaOH}$ in 200 mL H O ) followed, if necessary, by heating with a heat gun.

For column chromatography, silica gel 60 from Merck with a particle size of $0.040-0.063 \mathrm{~mm}$ was used.
