Figure S5. Determination of cellular dissociation constants ( $K_{D}$ ). (A) EGFR positive (MDA-MB-468 and A431) and EGFR negative (MCF-7) cells were incubated with Fcabs at different concentration followed by staining with AF488-labeled detection antibody, washing and cytometer analysis as described in Figure S4. Varying binding saturation levels between MDA-MB-468 and A431 cells reflect distinct cell specific EGFR expression densities. Dose response curves were fitted using the asymmetric (five parameter) fitting function of GraphPad Prism (GraphPad Software, Inc.) to obtain $\mathrm{K}_{\mathrm{D}}$. (B) Cellular dissociation constants of Fcabs are in good agreement with $K_{D}$ values derived from binding to recombinant EGFR via BLI (Table 2) and literature data ${ }^{[1]}$.

## 5. Cellular uptake assay

For our cellular uptake study we used a pH-dependent fluorophore (pHAb-dye) based assay. ${ }^{[2]}$ We directly labeled constructs with pHAb-dye by applying random lysine coupling and acquired their intracellular accumulation kinetics on cells by measuring the fluorescence increase over time generated when constructs reach the acidic endosome and/or lysosome. Importantly, the fluorescence of randomly coupled pHAb-dye molecules could be altered by pHAb-dye local molecular environment (Figure S6C) probably resulting in a non-linear relationship between the number of coupled pHAb-dye molecules and the individual fluorescence of a construct. ${ }^{[2-4]}$ To consider this, we developed a method similar to Wang et al. to derive a fluorescence- and absorption-based degree of pHAb -dye labeling ( $\mathrm{DOL}^{\mathrm{F}}$ and $\mathrm{DOL}^{\mathrm{A}}$ ) from $\mathrm{SE}-$ HPLC data. ${ }^{[5]}$ The SE-HPLC method has the advantage to simultaneously analyze DOL ${ }^{\text {F }}$ and DOL ${ }^{\text {A }}$ as well as aggregation and purification (free pHAb -dye) status of the labeled construct. The $\mathrm{DOL}^{\mathrm{F}}$ value of each $\mathrm{pHAb}-$ dye labeled construct can then be used to normalize fluorescence values of intracellular accumulation kinetics.

In the following a detailed description of the method is given. Figure S6D summarizes the method in short.

## SE-HPLC analysis

SE-HPLC was performed on a 1260 Infinity device from Agilent Technologies equipped with a diode array (DAD) and a fluorescence (FLD) detector module and either a TSKgel SuperSW3000 or a SuperSW2000 column. The mobile phase consisted of 50 mM sodium phosphate, 400 mM sodium perchlorate, pH 6.3 and its flow rate was set to $0.35 \mathrm{~mL} / \mathrm{min}$. The DAD was set to detect absorption at 280 nm (aromatic amino acids) and 535 nm (pHAb-dye). The excitation and emission wavelengths of the FLD were set to 535 nm and 566 nm to record fluorescence of pHAb-dye (Figure S6B).

Free pHAb-dye, pHAb-dye conjugated proteins and the corresponding unconjugated proteins were then analyzed by SE-HPLC. Figure S7 depicts exemplarily the resulting chromatograms for unconjugated protein, free pHAb-dye and pHAb-dye conjugated protein. In a next step, the molar extinction or fluorescence coefficients were derived from these data.

A

B

C

Factors that can influence fluorophore quantum yield include:
self-quenching by proximate fluorophores
quenching by other species, e.g. tryptophan
solvent accessibility / shielding by surrounding protein structure - local pH
D

Figure S6. pHAb-dye labeling and degree of labeling ( $D O L^{F}, D^{A} L^{A}$ ) determination (A) Structure of pHAb amine reactive dye 2 carrying an NHS ester group which can react with the $\varepsilon$-amino group of lysine. (B) Absorption and fluorescence spectra of pHAb dye in SE-HPLC buffer ( pH 6.3 ). (C) Proteins are labeled with pHAb-dye via random lysine coupling. Several factors can impact fluorophore quantum yield. ${ }^{[4]}$ (D) Overview of the established SE-HPLC method to determine the DOL ${ }^{F}$ and DOL ${ }^{A}$ value. Unconjugated proteins, free pHAb-dye and pHAb-dye conjugates were analyzed by an SE-HPLC device equipped with a diode array (DAD) and a fluorescence (FLD) detector. The molar extinction coefficients (MEC) of unconjugated protein and free pHAb-dye as well as the molar fluorescence coefficient (MFC) of free pHAb-dye were calculated from peak areas and the injected amount of substance. MEC and MFC were then used to calculate the amount of conjugated fluorescent pHAb-dye and the amount of protein from pHAb-dye conjugate peak areas. Finally, $\mathrm{DOL}^{F}$ and $\mathrm{DOL}^{A}$ can be derived from these data.

Figure S7. SE-HPLC analysis for the determination of the DOL ${ }^{F}$ and DOLA ${ }^{\text {A }}$, exemplarily shown for a pHAb-dye conjugated Fcab. (A) Unconjugated Fcab does not absorb light at 535 nm . (B) Hence, Fcab does not show fluorescence at 566 nm when excited at 535 nm (pHAb-dye absorption maximum). (C) Absorption of Fcab at 280 nm (aromatic amino acids). Fcab (54 kDa) elutes at 9.3 min . (D) Absorption of free pHAb-dye at its absorption maximum at 535 nm . According to its smaller size, free pHAb-dye ( $786 \mathrm{~g} / \mathrm{mol}$, carboxylic acid form) elutes later at 11.2 min . (E) Fluorescence at 566 nm (pHAb-dye fluorescence maximum) of free pHAb-dye when excited at 535 nm . (F) Free pHAb-dye absorbs also at 280 nm . The smaller peak at 11.8 min is caused by buffer components and was neglected for peak integration. (G) Absorption at 535 nm of Fcab-pHAb conjugate. The first peak marked in red represents the absorption of conjugated pHAb-dye molecules while the second peak marked in blue shows free pHAb-dye which could not be removed entirely by Zeba ${ }^{\text {TM }}$ spin desalting column purification. (H) Fluorescence at 566 nm of Fcab-pHAb conjugate. The peak depicted in red shows fluorescence of conjugated pHAb-dye while the blue peak shows fluorescence of free pHAb-dye. When comparing the peak area of fluorescence and absorption peaks ( 535 nm ), fluorescence of conjugated pHAb-dye is much lower with respect to free pHAb-dye. This confirms influences of the local molecular environment on fluorophore quantum yield. (I) Absorption of Fcab-pHAb at 280 nm is composed of the absorption of its protein and pHAb-dye components.

## Calculating molar extinction / fluorescence coefficient (MEC/MFC) of unconjugated protein and free pHAb-dye from SE-HPLC peak area

MEC/MFC of unconjugated protein and free pHAb-dye were calculated from SE-HPLC peak areas. Exemplary chromatograms can be found in Figure S7C (unconjugated protein) and Figure S7D-F (free pHAb-dye). Relevant peaks were integrated using the ChemStation analysis software by Agilent. From the corresponding peak area, the $\mathrm{MEC}_{280 n \mathrm{~m}}$ of the unconjugated protein and the $\mathrm{MEC}_{535 n \mathrm{~nm}} / \mathrm{MFC}_{566 n \mathrm{~nm}}$ of free pHAb-dye could be determined applying the following equation derived from Wang et al. ${ }^{[5]}$

$$
\begin{equation*}
\varepsilon_{i}=\frac{A r \cdot F}{l \cdot c \cdot v_{i n j}} \tag{1}
\end{equation*}
$$

where $\varepsilon_{i}$ is the MEC or MFC at wavelength $\lambda_{i}, A r$ is the calculated peak area, $F$ is the SE-HPLC flow rate, $l$ is the flow cell path length, $c$ is the concentration of the injected sample, and $u_{\text {inj }}$ is the injected sample volume. Table S1 summarizes the resulting MEC and MFC of unconjugated proteins and free pHAb-dye.

Table S1. Molar extinction / fluorescence coefficient at different wavelengths. MEC and MFC are given as the mean $\pm$ SD. Different volumes of unconjugated protein or free pHAb -dye solution were injected in three consecutive SE-HPLC runs and the resulting peak areas were used to calculate MEC or MFC from equation (1). For example, when injecting $v_{i n j}=7.5 \mu \mathrm{~L}$ of $c=18.3 \mu \mathrm{M}$ Fcab a single peak with a peak area $A r_{280 n m}$ of 1825 eluted at 9.3 min (Figure S7C). With a constant SE-HPLC flow rate of $F=5.8 \mu \mathrm{~L} / \mathrm{s}$, a $\mathrm{MEC}_{280 \mathrm{~mm}}$ of $77122(\mathrm{mM} \cdot \mathrm{cm})^{-1}$ was calculated.

| analyte | $\begin{gathered} \mathrm{MEC}_{280 \mathrm{~nm}} \\ {[\mathrm{mM} \cdot \mathrm{~cm}]^{-1}} \end{gathered}$ | $\begin{gathered} \mathrm{MEC}_{535 \mathrm{~nm}} \\ {[\mathrm{mM} \cdot \mathrm{~cm}]^{-1}} \end{gathered}$ | $\begin{gathered} \mathrm{MFC}_{566 n \mathrm{~m}} \\ {[\mathrm{mM} \cdot \mathrm{~cm}]^{-1}} \end{gathered}$ |
| :---: | :---: | :---: | :---: |
| Fcab-1 | $94582 \pm 685$ | - | - |
| Fcab-2 | $94608 \pm 1$ | - | - |
| Fcab-3 | $96964 \pm 155$ | - | - |
| huFc | $75217 \pm 306$ | - | - |
| C-Fab | $72828 \pm 26$ | - | - |
| C-IgG | $107610 \pm 182$ | - | - |
| free pHAb -dye | $14825 \pm 257$ | $60813 \pm 823$ | $103746 \pm 3003$ |

## Calculating the DOL ${ }^{F}$ and DOL $^{A}$ from SE-HPLC peak area of pHAb-dye conjugated protein and MEC/MFC

To calculate the DOL $^{\mathrm{F}}$ value from a pHAb-dye labeled construct, the molar amount of conjugated fluorescent pHAb-dye ( $n_{\text {pHAb, } 566 \mathrm{~nm}}$ ) and protein ( $n_{\text {protein,280nm }}$ ) was calculated first. Therefore, pHAb-dye labeled constructs were analyzed by SE-HPLC and the absorption and fluorescence peak area of conjugated pHAb-dye (Figure S7G-H peaks marked in red), as well as peak area from absorption at 280 nm (Figure S7I) were calculated. Absorption at 280 nm is caused not only by the protein structure but also by the conjugated pHAb-dye (Figure S7F). To calculate the amount of injected protein from this peak, the peak area that is contributed by pHAb-dye must be subtracted. The portion of pHAb-dye absorption at 280 nm can be derived from its peak area at $535 \mathrm{~nm}\left(A r_{535 \mathrm{~nm}}\right)$ and subtracted from total peak area at 280 nm ( $A r_{280 \mathrm{~nm}}$ ) as shown in equation (2)

$$
\begin{equation*}
A r_{280 \mathrm{~nm}, \text { corrected }}=A r_{280 \mathrm{~nm}}-\left(A r_{535 \mathrm{~nm}} \cdot \frac{M E C_{p H A b, 280 \mathrm{~nm}}}{M E C_{p H A b, 535 \mathrm{~nm}}}\right) \tag{2}
\end{equation*}
$$

Subsequently, the amount of injected protein can be calculated from the corrected peak area ( $A r_{280 \mathrm{~nm}, \text { corrected }}$ ) by equation (3)

$$
\begin{equation*}
n_{\text {protein }, 280 \mathrm{~nm}}=\frac{A r_{280 \mathrm{~nm}, \text { corrected }} \cdot F}{M E C_{\text {protein }, 280 \mathrm{~nm}}} \tag{3}
\end{equation*}
$$

Similarly, the amount of conjugated fluorescent pHAb-dye can be calculated from the peak area of its fluorescence signal at $566 \mathrm{~nm}\left(A r_{566 \mathrm{~nm}}\right)$ :

$$
\begin{equation*}
n_{p H A b, 566 n m}=\frac{A r_{566 n m} \cdot F}{M F C_{p H A b, 566 n m}} \tag{4}
\end{equation*}
$$

The ratio between the amount of conjugated fluorescent pHAb-dye molecules and protein defines the $D L^{F}$ value for the individual fluorescence of a construct:

$$
\begin{equation*}
D O L^{F}=\frac{n_{p H A b, 566 \mathrm{~nm}}}{n_{\text {protein, } 280 \mathrm{~nm}}} \tag{5}
\end{equation*}
$$

In analogy, the absolute amount of conjugated pHAb-dye molecules per protein ( $\mathrm{DOL}^{\mathrm{A}}$ ) can be calculated from the peak area of pHAb -dye absorption at 535 nm applying equation (6) and (7).

$$
\begin{gather*}
n_{p H A b, 535 n m}=\frac{A r_{535 \mathrm{~nm}} \cdot F}{M E C_{p H A b, 535 \mathrm{~nm}}}  \tag{6}\\
D O L^{A}=\frac{n_{p H A b, 535 \mathrm{~nm}}}{n_{\text {protein,280nm }}} \tag{7}
\end{gather*}
$$

The SE-HPLC chromatograms of relevant pHAb-dye conjugates as well as DOL ${ }^{F}$ and DOL $^{A}$ values are shown in Figure S8. In line with our expectations, the number of fluorescent pHAb-dye molecules per protein $\left(D O L^{F}\right)$ is lower compared to the absolute number of conjugated pHAb-dye molecules (DOL ${ }^{A}$ ). Since fluorescence represents the readout of the cellular uptake assay, fluorescence values can be normalized to their $\mathrm{DOL}^{\mathrm{F}}$ value to account for the individual fluorescence of pHAb-dye labeled constructs. Consequently, the $D O L^{F}$ and cell number normalized intracellular accumulation rates allow for comparability.

Figure S9. Cellular uptake kinetics of pHAb-dye labeled constructs. (A) Cellular accumulation time series exemplarily shown for Fcab-1-pHAb on MDA-MB-468 cells. Cells were incubated at $37{ }^{\circ} \mathrm{C}, 80 \%$ humidity and $5 \% \mathrm{CO}_{2}$ with 100 nM Fcab-1-pHAb and RFP channel images (ex.: 531 nm , em.: 593 nm ) were recorded every 2 h for 26 h using a Cytation 5 cell imaging reader (BioTek) equipped with DAPI and RFP filter cubes and a BioSpa 8 automated incubator (BioTek). (B) The total fluorescence intensity of images is normalized to cell-number and DOLF value of the pHAb-dye labeled construct and plotted over time to derive normalized intracellular accumulation rates from slopes of linear regression (GraphPad Software, Inc.). Subsequently, the relative intracellular accumulation can be calculated from these rates. (C) Normalized cellular uptake rates derived from described imager-based assay could be verified in a second FACS-based cellular uptake assay employing the same pHAb-dye labeled constructs. (D) Relative intracellular accumulation in MDA-MB-468 derived from FACS-based assay is in good agreement with the imaging-based cellular uptake data (Figure 1).

## 6. Generation of MMAE conjugates

Figure S10. Conjugation and purification strategy exemplarily shown for Fcab-MMAE conjugates. (A) MMAE conjugates were generated by enzymatic transglutaminase conjugation. After conjugation, excess of microbial transglutaminase (mTG) and Gly $3^{-}$ Val-Cit-MMAE (1) was removed by preparative SEC. (B) Purification of transglutaminase conjugated MMAE constructs by preparative SEC, exemplarily shown for Fcab-2-MMAE and huFc-MMAE. Fractions containing conjugated proteins (and nonconjugated species) were pooled, concentrated, sterile filtered and subjected to analytics.

## 7. Analytics of MMAE conjugates

Figure S11. Chromatographic characterization of generated MMAE conjugates exemplarily shown for Fcab-1-MMAE, Fcab-2-MMAE Fcab-3-MMAE and huFc-MMAE. (A) Analytical size exclusion SE-HPLC shows a distinct single peak demonstrating formation of monomeric drug conjugates without aggregates. Signal intensity represents absorption at 214 nm (B) Reversed phase RP-HPLC reveals conjugation of Gly $y_{3}$-Val-Cit-MMAE 1. RP-DAR is calculated from peak areas of individual DAR species (Fcab-1-MMAE RP-DAR 2.6; Fcab-2-MMAE RP-DAR 2.5; Fcab-3-MMAE RP-DAR 2.5; huFc-MMAE RP-DAR 2.0). For example, 25 \% relative peak area of DAR 1 species and 75 \% relative peak area of DAR 2 species reveals a final RP-DAR of 1.75. Signal intensity represents absorption at 214 nm .

Table S2. Hydrophobic interaction chromatography (HI-HPLC) retention times ( $\mathrm{t}_{\mathrm{R}}$ ) of unconjugated parental construct and DAR 1.0-3.0 MMAE-conjugate species. Relative retention time (RRT) refers to the ratio between the $t_{R}$ of the DAR species indicated in the table below and the $t_{R}$ of the unconjugated parental molecule. HI-HPLC RRT is an indicator for shielding of hydrophobic payloads such as MMAE and can be used to estimate the accessibility of linker-drugs for serum proteases like murine carboxylesterase. ${ }^{[6]}$

| conjugate | HI-HPLC |  |  |  |  |

Figure S12. DAR determination of Fcab-MMAE conjugates by mass spectrometry. Deconvoluted MS spectra showing groups of differently glycosylated heavy chains ( HC ) carrying $0-3 \mathrm{Gly}{ }_{3}$-Val-Cit-MMAE (1). TIC area of HC species carrying $0-3$ linker payloads were used to calculate the MS-DAR.

## 8. Receptor binding properties of MMAE conjugates

Table S3. Kinetic parameters EGFR binding. Dissociation constants ( $\mathrm{K}_{\mathrm{D}}$ ), on- $\left(\mathrm{k}_{\mathrm{on}}\right)$ and off-rates ( $\mathrm{K}_{\text {off }}$ ) were measured at pH 7.4 by BLI using recombinantly produced EGFR. Errors are standard errors from fitting using FortéBio data analysis software 9.1. Fitting quality is characterized by $\mathrm{R}^{2}$.

Figure S13. Receptor binding BLI sensorgrams of unconjugated Fcabs, Cetuximab variants and respective MMAE conjugates (A) EGFR binding analysis. Association and dissociation were recorded at pH 7.4 and fitted by a 1:1 global full-fit binding model. (B) FcRn binding analysis. Association and dissociation of analytes were recorded at pH 6.0 and fitted by a $1: 1$ global partialdissociation model. Fittings are shown in red. For each sensorgram, the highest concentration of analyte during association and its dilution factor are given.
